Abstract

In this document, we introduce PyCSP³, a Python library that allows us to write models of combinatorial constrained problems in a natural and declarative way. Currently, with PyCSP³, you can write models of satisfaction and optimization problems. More specifically, you can build CSP (Constraint Satisfaction Problem) and COP (Constraint Optimization Problem) models. Importantly, there is a complete separation between modeling and solving phases: you write a model, you compile it (while providing some data) in order to obtain an XCSP³ instance (file), and you solve that problem instance with a constraint solver. PyCSP³ is inspired from both JvCSP³ [22] and Numberjack [18]. It has also connections with CPpy [17].

The main ingredients of the complete tool chain we propose for solving combinatorial constrained problems are:

- PyCSP³: a Python library for modeling constrained problems, which is described in this document (or equivalently, JvCSP³, a Java-based API)
- XCSP³: an intermediate format used to represent problem instances while preserving structure of models

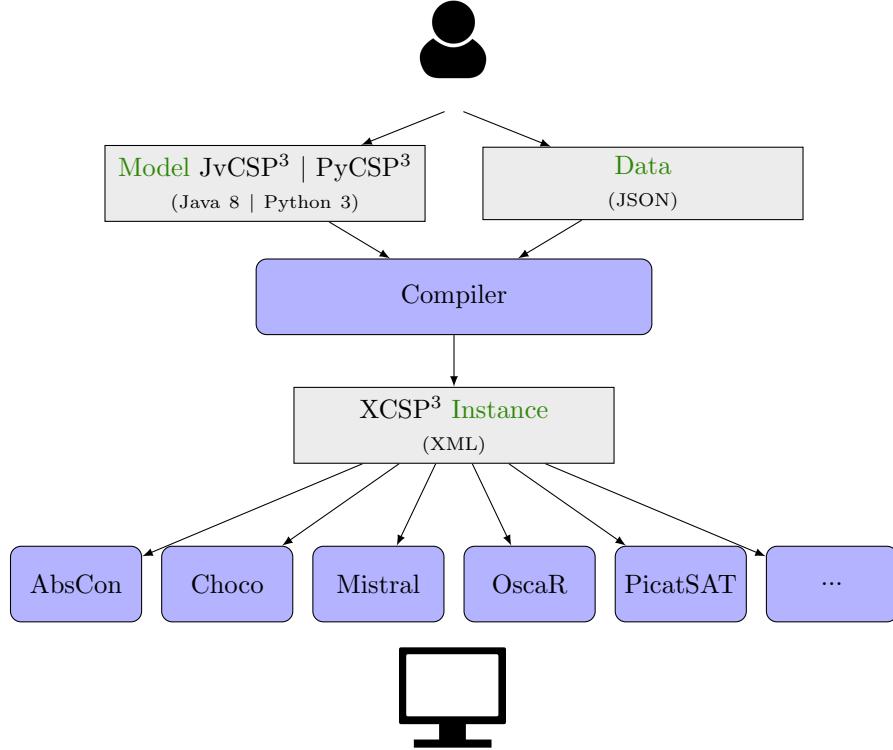

Figure 1: Complete process for modeling and solving combinatorial constrained problems.

For modeling, as indicated above, the user can choose between two well-known languages (Python and Java), but this document focuses on Python. As shown in Figure 1, the user who wishes to solve a combinatorial constrained problem has to:

1. write a model using either the Python library PyCSP³ (i.e., write a Python file) or the Java modeling API JvCSP³ (i.e., write a Java file)
2. provide a data file (in JSON format) for a specific problem instance to be solved
3. compile both files (model and data) so as to generate an XCSP³ instance (file)
4. solve the XCSP³ file (problem instance under format XCSP³) by using constraint solvers like, e.g., AbsCon, Choco, OscaR or PicatSAT

This approach has many advantages:

- Python (and Java), JSON, and XML are robust mainstream technologies
- Using JSON for data permits to have a unified notation, easy to read for both humans and machines

- using Python 3 (or Java 8) for modeling allows the user to avoid learning again a new programming language
- Using a coarse-grained XML structure permits to have compact and readable problem descriptions, easy to read for both humans and machines

Remark 1 *Using JSON instead of XML for representing instances is possible but has some drawbacks, as explained in an appendix of XCSP³ Specifications [5].*

Chapter 1

Illustrative Models in PyCSP³

Warning. In this chapter, we introduce PyCSP³ by means of various problems that illustrate the main ingredients of the library. We also usually show the result of compiling PyCSP³ models into XCSP³, although that part can be totally ignored.

1.1 Single Problems

We propose to start discovering PyCSP³ with some very simple problems.

1.1.1 A Simple Riddle

Remember that when you were young, you were used to play at riddles, some of them having a mathematical background as for example:

Which sequence of successive four integer numbers sum up to 14?

If you were already familiar with Mathematics, maybe you were able to formalize this riddle by:

- introducing four integer variables:
 - $x_1 \in \mathbb{N}, x_2 \in \mathbb{N}, x_3 \in \mathbb{N}, x_4 \in \mathbb{N}$
- introducing the following mathematical equations (constraints):
 - $x_1 + 1 = x_2$
 - $x_2 + 1 = x_3$
 - $x_3 + 1 = x_4$
 - $x_1 + x_2 + x_3 + x_4 = 14$

This is a CSP (Constraint Satisfaction problem) instance, involving four integer variables, three binary constraints (i.e., constraints involving exactly two distinct variables) and one quaternary constraint (i.e., constraint involving exactly four distinct variables).

After a rough analysis, we can decide to set 0 as lower bound and 14 as upper bound for the possible values of the integer variables because, by using that interval of values, we are absolutely

certain of not losing any solutions while avoiding to reason with infinite sets of values. We then obtain the following PyCSP³ model in a file called 'Riddle.py':

PyCSP³ Model 1

```
from pycsp3 import *

x1 = Var(range(15))
x2 = Var(range(15))
x3 = Var(range(15))
x4 = Var(range(15))

satisfy(
    x1 + 1 == x2,
    x2 + 1 == x3,
    x3 + 1 == x4,
    x1 + x2 + x3 + x4 == 14
)
```

In this Python file, after the first import statement, we declare stand-alone variables by using the PyCSP³ function `Var()`. Here, we declare four variables called `x1`, `x2`, `x3`, and `x4`, each one with the set of integers $\{0, 1, \dots, 14\}$ as domain.

Remark 2 *Currently in PyCSP³, we can only define integer and symbolic variables, i.e., variables with a finite set of integers or symbols (strings).*

To define the domain of a variable, we can simply list values, or use `range()`. For example:

```
w = Var(range(15))
x = Var(0, 1)
y = Var(0, 2, 4, 6, 8)
z = Var("a", "b", "c")
```

declares four variables corresponding to:

- o $w \in \{0, 1, \dots, 14\}$
- o $x \in \{0, 1\}$
- o $y \in \{0, 2, 4, 6, 8\}$
- o $z \in \{"a", "b", "c"\}$

Values can be directly listed as above, or given in a set as follows:

```
w = Var({range(15)})
x = Var({0, 1})
y = Var({0, 2, 4, 6, 8})
z = Var({"a", "b", "c"})
```

It is also possible to name the parameter `dom` when defining the domain:

```
w = Var(dom=range(15))
x = Var(dom={0, 1})
y = Var(dom={0, 2, 4, 6, 8})
z = Var(dom={"a", "b", "c"})
```

Finally, it is of course possible to use comprehension lists. For example, for `y`, we can write:

```
y = Var(i for i in range(10) if i % 2 == 0)
```

or equivalently:

```
y = Var({i for i in range(10) if i % 2 == 0})
```

or equivalently:

```
y = Var(dom={i for i in range(10) if i % 2 == 0})
```

Now, let us turn to constraints. When constraints must be imposed on variables, we say that these constraints must be satisfied. Then, to impose (post) them, we call the PyCSP³ function `satisfy()`, with each constraint passed as a parameter (and so, with comma used as a separator between constraints). In our example, we have posted four constraints to be satisfied. These constraints are given in `intension`, by using classical arithmetic, relational and logical operators. Note that for forcing equality, we need to use '==' in Python (the operator '=' used for assignment cannot be redefined). In Tables 1.1 and 1.2, you can find the available operators and functions. In Table 1.3, you can find a few examples of `intension` constraints.

Once you have a PyCSP³ model, you can compile it in order to get an XCSP³ file that can be solved by a constraint solver. The command is as follows:

```
python3 Riddle.py
```

The content of the XCSP³ file is:

```
<instance format="XCSP3" type="CSP">
<variables>
    <var id="x1"> 0..14 </var>
    <var id="x2"> 0..14 </var>
    <var id="x3"> 0..14 </var>
    <var id="x4"> 0..14 </var>
</variables>
<constraints>
    <intension> eq(add(x1,1),x2) </intension>
    <intension> eq(add(x2,1),x3) </intension>
    <intension> eq(add(x3,1),x4) </intension>
    <intension> eq(add(x1,x2,x3,x4),14) </intension>
</constraints>
</instance>
```

The variables in our model have been declared independently, but it is possible to declare them in a one-dimensional array. This gives a new PyCSP³ model (variant) in a file called 'Riddle2.py':

PyCSP³ Model 2

```
from pycsp3 import *

# x[i] is the ith integer of the sequence
x = VarArray(size=4, dom=range(15))

satisfy(
    x[0] + 1 == x[1],
    x[1] + 1 == x[2],
    x[2] + 1 == x[3],
    x[0] + x[1] + x[2] + x[3] == 14
)
```

and the XCSP³ file obtained after compilation:

```
python3 Riddle2.py
```

is:

```
<instance format="XCSP3" type="CSP">
<variables>
    <array id="x" note="x[i] is the ith integer of the sequence" size="[4]">
        0..14
    </array>
</variables>
```

Arithmetic Operators	
+	addition
-	subtraction
*	multiplication
//	integer division
%	remainder
**	power

Relational Operators	
<	Less than
<=	Less than or equal
>=	Greater than or equal
>	Greater than
!=	Different from
==	Equal to

Set Operators	
in	membership
not in	non membership

Logical Operators	
~	logical not
	logical or
&	logical and
^	logical xor

Table 1.1: Operators that can be used to build expressions (predicates) of `intension` constraints. Integer values 0 and 1 are respectively equivalent to Boolean values *false* and *true*.

Functions	
<code>abs()</code>	absolute value of the argument
<code>min()</code>	minimum value of 2 or more arguments
<code>max()</code>	maximum value of 2 or more arguments
<code>conjunction()</code>	conjunction of 2 or more arguments
<code>disjunction()</code>	disjunction of 2 or more arguments
<code>imply()</code>	implication between 2 arguments
<code>iff()</code>	equivalence between 2 or more arguments
<code>ift()</code>	ift(b,u,v) returns u if b is true, v otherwise

Table 1.2: Functions that can be used to build expressions (predicates) of `intension` constraints.

$x + y < 10$
$x * 2 - 10 * y + 5 == 100$
$\text{abs}(z[0] - z[1]) >= 2$
$(x == y) \mid (y == 0)$
$\text{disjunction}(x < 2, y < 4, x > y)$
$\text{imply}(x == 0, y > 0)$
$\text{iff}(x > 0, y > 0)$
$(x == 0) \wedge (y == 1)$
$\text{ift}(x == 0, 5, 10)$

Table 1.3: A few examples of `intension` constraints.

```
<constraints>
  <intension> eq(add(x[0],1),x[1]) </intension>
  <intension> eq(add(x[1],1),x[2]) </intension>
  <intension> eq(add(x[2],1),x[3]) </intension>
  <intension> eq(add(x[0],x[1],x[2],x[3]),14) </intension>
</constraints>
</instance>
```

Here, we declare a one-dimensional array of variables: its name (`id`) is x , its size (`length`) is 4, and each of its variables has $\{0, 1, \dots, 14\}$ as domain. Note that we use $x[i]$ for referring to the $(i + 1)$ th variable of the array (since indexing starts at 0) and that any comment put in the line preceding the declaration of a variable (or variable array) is automatically inserted in the XCSP³ file. The PyCSP³ function for declaring an array of variables is `VarArray()` that requires two named parameters `size` and `dom`. For declaring a one-dimensional array of variables, the value of `size` must be an integer (or a list containing only one integer), for declaring a two-dimensional array of variables, the value of `size` must be a list containing exactly two integers, and so on.

In some situations, you may want to declare variables in an array with different domains. For a one-dimensional array, you can give the name of a function that accepts an integer i and returns the domain to be associated with the variable at index i in the array. For a two-dimensional array, you can give the name of a function that accepts a pair of integers (i, j) and returns the domain to be associated with the variable at indexes i, j in the array. And so on. For example, suppose that we have analytically deduced that the two first variables of the array x must be assigned a value strictly less than 6 and the two last variables of the array x must be assigned a value strictly less than 9. We can write:

PyCSP³ Model 3

```
from pycsp3 import *

def domain_x(i):
    return range(6) if i < 2 else range(9)

# x[i] is the ith integer of the sequence
x = VarArray(size=4, dom=domain_x)

satisfy(
    x[0] + 1 == x[1],
    x[1] + 1 == x[2],
    x[2] + 1 == x[3],
    x[0] + x[1] + x[2] + x[3] == 14
)
```

The XCSP³ file obtained after compilation is:

```

<instance format="XCSP3" type="CSP">
  <variables>
    <array id="x" note="x[i] is the ith integer of the sequence" size="[4]">
      <domain for="x[0] x[1]"> 0..5 </domain>
      <domain for="x[2] x[3]"> 0..8 </domain>
    </array>
  </variables>
  <constraints>
    <intension> eq(add(x[0],1),x[1]) </intension>
    <intension> eq(add(x[1],1),x[2]) </intension>
    <intension> eq(add(x[2],1),x[3]) </intension>
    <intension> eq(add(x[0],x[1],x[2],x[3]),14) </intension>
  </constraints>
</instance>

```

Instead of calling named functions, we can use lambda functions. This gives:

PyCSP³ Model 4

```

from pycsp3 import *

# x[i] is the ith integer of the sequence
x = VarArray(size=4, dom=lambda i: range(6) if i < 2 else range(9))

satisfy(
    x[0] + 1 == x[1],
    x[1] + 1 == x[2],
    x[2] + 1 == x[3],
    x[0] + x[1] + x[2] + x[3] == 14
)

```

Let us keep analyzing the code of our model. Because the three binary constraints are similar, one may wonder if we couldn't post these constraints together (in a list). This is indeed possible by using a comprehension list:

PyCSP³ Model 5

```

from pycsp3 import *

# x[i] is the ith integer of the sequence
x = VarArray(size=4, dom=range(15))

satisfy(
    [x[i] + 1 == x[i + 1] for i in range(3)],
    x[0] + x[1] + x[2] + x[3] == 14
)

```

and the XCSP³ file obtained after compilation is:

```

<instance format="XCSP3" type="CSP">
  <variables>
    <array id="x" note="x[i] is the ith integer of the sequence" size="[4]">
      0..14
    </array>
  </variables>
  <constraints>
    <group>
      <intension> eq(add(%0,%1),%2) </intension>
      <args> x[0] 1 x[1] </args>
      <args> x[1] 1 x[2] </args>
      <args> x[2] 1 x[3] </args>
    </group>
  </constraints>
</instance>

```

```

</group>
<intension> eq(add(x[0],x[1],x[2],x[3]),14) </intension>
</constraints>
</instance>

```

Because of the presence of the comprehension list, we obtain a group of constraints in XCSP³: basically, we have a constraint template with several parameters identified by %, and one “concrete” constraint per element <args> providing the effective arguments. For more information about groups in XCSP³, see Chapter 10 in [XCSP³ Specifications](#). Of course, you can use the classical control structures of Python. So, an alternative way of writing the model is:

PyCSP³ Model 6

```

from pycsp3 import *

# x[i] is the ith integer of the sequence
x = VarArray(size=4, dom=range(15))

for i in range(3):
    satisfy(
        x[i] + 1 == x[i + 1]
    )

satisfy(
    x[0] + x[1] + x[2] + x[3] == 14
)

```

Finally, it seems more appropriate to represent the last constraint as a constraint **sum**. We can then call the PyCSP³ function **Sum()** that builds an object that can be compared for example with a value. This gives:

PyCSP³ Model 7

```

from pycsp3 import *

# x[i] is the ith integer of the sequence
x = VarArray(size=4, dom=range(15))

satisfy(
    [x[i] + 1 == x[i + 1] for i in range(3)],
    Sum(x) == 14
)

```

and the XCSP³ file obtained after compilation is:

```

<instance format="XCSP3" type="CSP">
<variables>
<array id="x" note="x[i] is the ith integer of the sequence" size="[4]">
    0..14
</array>
</variables>
<constraints>
<group>
    <intension> eq(add(%0,%1),%2) </intension>
    <args> x[0] 1 x[1] </args>
    <args> x[1] 1 x[2] </args>
    <args> x[2] 1 x[3] </args>
</group>
<sum>
    <list> x[] </list>

```

```

<condition> (eq,14) </condition>
</sum>
</constraints>
</instance>

```

1.1.2 Playing with Small Constraint Networks

When studying properties of constraint networks, it is frequent to draw some small constraint networks under the form of compatibility graphs (also called micro-structures). For example, Figure 1.1 presents the compatibility graph of a small constraint network P such that:

- o the set of variables of P is $\text{vars}(P) = \{x, y, z\}$, each variable having $\{a, b\}$ as domain;
- o the set of constraints of P is $\text{ctrs}(P) = \{\langle x, y \rangle \in \{(a, a), (b, b)\}, \langle x, z \rangle \in \{(a, a), (b, b)\}, \langle y, z \rangle \in \{(a, b), (b, a)\}\}$.

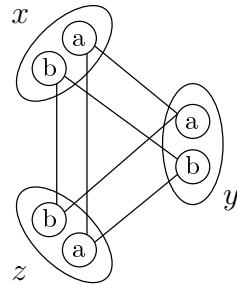

Figure 1.1: The compatibility graph of a small constraint network.

The interested reader can observe that the constraint network is arc-consistent (AC) but not path-inverse consistent (PIC). Don't worry! It doesn't matter here if you do not know anything about these properties. Anyway, the PyCSP³ model for our problem, in a file called Pic.py, is as follows:

PyCSP³ Model 8

```

from pycsp3 import *

x = Var("a", "b")
y = Var("a", "b")
z = Var("a", "b")

satisfy(
    (x, y) in {("a", "a"), ("b", "b")},
    (x, z) in {("a", "a"), ("b", "b")},
    (y, z) in {("a", "b"), ("b", "a")}
)

```

For compiling it, we execute:

```
python3 Pic.py
```

and the XCSP³ file obtained after compilation is:

```

<instance format="XCSP3" type="CSP">
<variables>
  <var id="x" type="symbolic"> a b </var>

```

```

<var id="y" type="symbolic"> a b </var>
<var id="z" type="symbolic"> a b </var>
</variables>
<constraints>
<extension>
<list> x y </list>
<supports> (a,a)(b,b) </supports>
</extension>
<extension>
<list> x z </list>
<supports> (a,a)(b,b) </supports>
</extension>
<extension>
<list> y z </list>
<supports> (a,b)(b,a) </supports>
</extension>
</constraints>
</instance>

```

Here, we declare three stand-alone symbolic variables (note how the domain of each of them is simply composed of the two symbols "a" and "b"). And we declare three binary constraints in `extension`. In PyCSP³, we simply use the operator `in` to represent such constraints: a tuple of variables representing the scope of the constraint is given at the left of the operator and a set of tuples of values is given at the right of the operator. This is basically what we write in mathematical form. Note that we use `in` when the constraint enumerates the allowed tuples (called `supports`) and `not in` when the constraint enumerates the forbidden tuples (called `conflicts`).

Now, suppose that instead of declaring symbolic variables, you prefer to declare integer variables. By replacing "a" by 0 and "b" by 1, you can write:

PyCSP³ Model 9

```

from pycsp3 import *

x = Var(0, 1)
y = Var(0, 1)
z = Var(0, 1)

satisfy(
    (x, y) in {(0, 0), (1, 1)},
    (x, z) in {(0, 0), (1, 1)},
    (y, z) in {(0, 1), (1, 0)}
)

```

which, when compiled, gives:

```

<instance format="XCSP3" type="CSP">
<variables>
<var id="x"> 0 1 </var>
<var id="y"> 0 1 </var>
<var id="z"> 0 1 </var>
</variables>
<constraints>
<extension>
<list> x y </list>
<supports> (0,0)(1,1) </supports>
</extension>
<extension>
<list> x z </list>
<supports> (0,0)(1,1) </supports>
</extension>
<extension>
<list> y z </list>

```

```

<supports> (0,1)(1,0) </supports>
</extension>
</constraints>
</instance>

```

Note that the scope of an `extension` constraint is expected to be given under the form of a tuple, but can be given under the form of a list too. Similarly, the table of an `extension` constraint is expected to be given under the form of a set, but can be given under the form a list too. This means that, for example, it is possible to write:

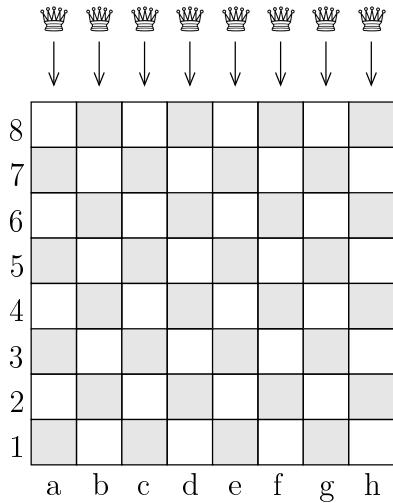

```
[x, y] in [(0, 0), (1, 1)]
```

1.2 Academic Problems

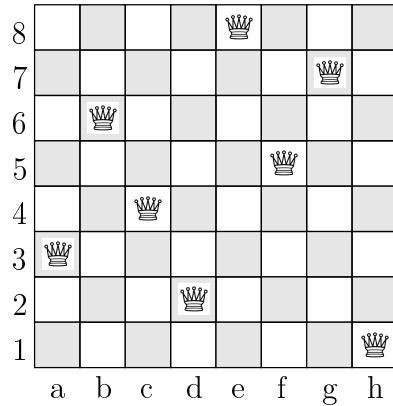

Contrary to single problems, academic problems require the introduction of some (elementary) pieces of data from the user.

1.2.1 Queens

The problem is stated as follows: can we put 8 queens on a chessboard such that no two queens attack each other? Two queens attack each other iff they belong to the same row, the same column or the same diagonal. An illustration is given by Figure 1.2.

(a) Puzzle

(b) Solution

Figure 1.2: Putting 8 queens on a chessboard

By considering boards of various size, the problem can be generalized as follows: can we put n queens on a board of size $n \times n$ such that no two queens attack each other? Contrary to previously introduced single problems, we have to deal here with a family of problem instances, each of them characterized by a distinct value of n . We can try to solve the 8-queens instance, the 10-queens instance, and even the 1000-queens instance.

For such problems, we have to separate the description of the model from the description of the data. In other words, we have to write a model with some kind of parameters. In PyCSP³, what you have to do is:

1. clearly identify the parameters of the problem (names and structures)

2. use these parameters in your model by using the fields of the predefined PyCSP³ object `data`
3. specify effective values of these parameters when you compile to XCSP³

In our case, we have only one integer parameter called n . If we associate a variable q_i with the i th row of the board, then we can simply post the following constraints:

$$q_i \neq q_j \wedge |q_i - q_j| \neq |i - j|, \forall i, j : 1 \leq i < j \leq n$$

This can be translated into a PyCSP³ model in a file 'Queens.py':

```
from pycsp3 import *

n = data.n

# q[i] is the column of the ith queen (at row i)
q = VarArray(size=n, dom=range(n))

satisfy(
    (q[i] != q[j]) & (abs(q[i] - q[j]) != abs(i - j))
    for i in range(n) for j in range(i + 1, n)
)
```

Note how the parameter n is given by a field of the predefined PyCSP³ object `data`; here, for simplicity, we prefer to copy its value in a local variable n . The intension constraints are given by a comprehension list (actually a generator, since brackets are omitted here although we could have inserted them).

Now, the question is: how can we solve a specific instance? The answer is: just compile the model while indicating with the option `-data` either the value for n or the name of a JSON file containing an object with a unique field n . In the former case, this gives for $n = 4$:

```
python3 Queens.py -data=4
```

and the XCSP³ file obtained after compilation is:

```
<instance format="XCSP3" type="CSP">
<variables>
  <array id="q" note="q[i] is the column of the ith queen (at row i)" size="[4]">
    0..3
  </array>
</variables>
<constraints>
  <group>
    <intension> and(ne(%0,%1),ne(abs(sub(%0,%1)),%2)) </intension>
    <args> q[0] q[1] 1 </args>
    <args> q[0] q[2] 2 </args>
    <args> q[0] q[3] 3 </args>
    <args> q[1] q[2] 1 </args>
    <args> q[1] q[3] 2 </args>
    <args> q[2] q[3] 1 </args>
  </group>
</constraints>
</instance>
```

In the latter case, just build a file 'queens-4.json' whose content is:

```
{  
  "n": 4  
}
```

and execute:

```
python3 Queens.py -data=queens-4.json
```

Remember that once you have an XCSP³ file, you can run any solver that recognizes this format: AbsCon, Choco, PicatSAT, OscaR, ...

At this point, you have been told that it could be a good idea to post `allDifferent` constraints; remember that an `allDifferent` constraint imposes that all involved variables (or expressions) must take different values. It is known that it suffices to post three constraints as in the following model:

PyCSP³ Model 11

```
from pycsp3 import *

n = data.n

# q[i] is the column of the ith queen (at row i)
q = VarArray(size=n, dom=range(n))

satisfy(
    # all queens are put on different columns
    AllDifferent(q),

    # no two queens on the same upward diagonal
    AllDifferent(q[i] + i for i in range(n)),

    # no two queens on the same downward diagonal
    AllDifferent(q[i] - i for i in range(n))
)
```

After compilation, we obtain:

```
<instance format="XCSP3" type="CSP">
<variables>
  <array id="q" note="q[i] is the column of the ith queen (at row i)" size="[4]">
    0..3
  </array>
</variables>
<constraints>
  <allDifferent note="all queens are put on different columns">
    q[]
  </allDifferent>
  <allDifferent note="no two queens on the same upward diagonal">
    add(q[0],0) add(q[1],1) add(q[2],2) add(q[3],3)
  </allDifferent>
  <allDifferent note="no two queens on the same downward diagonal">
    sub(q[0],0) sub(q[1],1) sub(q[2],2) sub(q[3],3)
  </allDifferent>
</constraints>
</instance>
```

Remark 3 In PyCSP³, most of the global constraints are posted by calling a function whose first letter is uppercase, as for example `AllDifferent()`, `Sum()`, and `Cardinality()`.

Maybe, you think that it is annoying of having several files for various model variants (have you observed how many frameworks generate hundreds and even thousands of files; this is crazy!). In fact, you can put different model variants in the same file by using the PyCSP³ function `variant()` that accepts a string as parameter (or nothing). When you compile, you can then indicate the name of the variant. Putting the two variants seen earlier in the same file 'Queens.py' gives:

PyCSP³ Model 12

```
from pycsp3 import *

n = data.n

# q[i] is the column of the ith queen (at row i)
q = VarArray(size=n, dom=range(n))

if not variant():
    satisfy(
        # all queens are put on different columns
        AllDifferent(q),

        # no two queens on the same upward diagonal
        AllDifferent(q[i] + i for i in range(n)),

        # no two queens on the same downward diagonal
        AllDifferent(q[i] - i for i in range(n))
    )
elif variant("bin"):
    satisfy(
        (q[i] != q[j]) & (abs(q[i] - q[j]) != abs(i - j))
        for i in range(n) for j in range(i + 1, n)
    )
```

To compile the main model (variant), just type:

```
python3 Queens.py -data=4
```

To compile the model variant "bin", just type:

```
python3 Queens.py -variant=bin -data=4
```

1.2.2 Board Coloration

The (chess)board coloration problem is to color all squares of a board composed of r rows and c columns such that the four corners of any rectangle in the board must not be assigned the same color. Importantly, we want to minimize the number of used colors.

Figure 1.3: Coloring Boards.

This time, we need two integer parameters `nRows` and `nCols`. For simplicity, their values (stored in two fields of the predefined PyCSP³ object `data`) are copied in two local variables `n` and `m`. After a very rough analysis, we can decide to use $n \times m$ as an upper bound of the number of used colors. This gives a PyCSP³ model in a file 'BoardColoration.py':

PyCSP³ Model 13

```
from pycsp3 import *

n, m = data.nRows, data.nCols

# x[i][j] is the color at row i and column j
x = VarArray(size=[n, m], dom=range(n * m))

satisfy(
    # at least 2 corners of different colors for any rectangle inside the board
    NValues(x[i1][j1], x[i1][j2], x[i2][j1], x[i2][j2]) > 1
    for i1 in range(n) for i2 in range(i1 + 1, n)
    for j1 in range(m) for j2 in range(j1 + 1, m)
)

minimize(
    Maximum(x)
)
```

Here, we declare a two-dimensional array of variables: its name is x , its size is $n \times m$ and each of its variables has $\{0, 1, \dots, n \times m - 1\}$ as domain. We need here to post several `notAllEqual` constraints. Actually, this constraint is a special case of the constraint `nValues`: we want that the number of different values taken by some variables (the scope of the constraint) is strictly greater than 1. This is given in the model by an expression involving the PyCSP³ function `NValues()`.

Finally, the objective function corresponds to the minimization of the maximum value taken by any variable in the two-dimensional array x . Because domains are all similar, this is indeed equivalent to minimize the number of used colors. For an optimization problem, you can call either the PyCSP³ function `minimize()` or the PyCSP³ function `maximize()`. You can use different kinds of parameters:

- a stand-alone variable
- a general arithmetic expression, like in $u * 3 + v$ where u and v are two variables
- a sum over a list (array) of variables by using the function `Sum()`, like in `Sum(x)`
- a dot product, like in $[u, v, w] * [2, 4, 3]$ where u, v and w are three variables
- a minimum by using the function `Minimum()`, like in `Minimum(x)`
- a maximum by using the function `Maximum()`, like in `Maximum(x)`
- a number of different values by using the function `NValues()`, like in `NValues(x)`

To solve a specific instance, as usually, we have first to compile the model while indicating with the option `-data` either the values for `nRows` and `nCols` or the name of a JSON file containing an object with two fields `nRows` and `nCols`. In the former case, this gives for `nRows=3` and `nCols=4`:

```
python3 BoardColoration.py -data=[3,4]
```

Certainly, you wonder how values are associated with the fields of the predefined PyCSP³ object `data`. Actually, the order of occurrences of these fields in the model (file) is used. The first occurrence of a field of `data` in 'BoardColoration.py' is `data.nRows`, then it is `data.nCols`. So, we have automatically `data.nRows=3` and `data.nCols=4`.

However, you can relax this requirement by using names when specifying data, as for example, in:

```
python3 BoardColoration.py -data=[nCols=4,nRows=3]
```

The XCSP³ file obtained after compilation is:

```

<instance format="XCSP3" type="COP">
  <variables>
    <array id="x" size="[3][4]" note="x[i][j] is the color at row i and col j">
      0..11
    </array>
  </variables>
  <constraints>
    <group note="at least 2 corners of different colors for any rectangle">
      <nValues>
        <list> %... </list>
        <condition> (gt,1) </condition>
      </nValues>
      <args> x[0][0] x[0][1] x[1][0] x[1][1] </args>
      <args> x[0][0] x[0][2] x[1][0] x[1][2] </args>
      ...
      <args> x[1][1] x[1][2] x[2][2] x[2][3] </args>
    </group>
  </constraints>
  <objectives>
    <minimize type="maximum"> x[] [] </minimize>
  </objectives>
</instance>

```

We can also build a file “board-3-4.json” whose content is:

```
{
  "nRows": 3,
  "nCols": 4
}
```

and execute:

```
python3 BoardColoration.py -data=board-3-4.json
```

As a matter of fact, this problem has many symmetries. It is known that we can break variable symmetries by posting a lexicographic constraint between any two successive rows and any two successive columns. For posting lexicographic constraints, we can use the PyCSP³ functions `LexIncreasing()` and `LexDecreasing()`. Besides, we can use two optional named parameters `strict` and `matrix` whose default values are `false`. When `matrix` is set to `True`, it means that the constraint must be applied on each row and each column of the specified two-dimensional array. On the other hand, it is relevant to tag this constraint because it clearly informs us that it is inserted for breaking symmetries: tagging is made possible by putting in a comment line an expression of the form `tag()`, with a token (or a sequence of tokens separated by a whitespace) between parentheses. The model is now:

PyCSP³ Model 14

```

from pycsp3 import *

n, m = data.nRows, data.nCols

# x[i][j] is the color at row i and column j
x = VarArray(size=[n, m], dom=range(n * m))

satisfy(
    # at least 2 corners of different colors for any rectangle inside the board
    [NValues(x[i1][j1], x[i1][j2], x[i2][j1], x[i2][j2]) > 1
     for i1 in range(n) for i2 in range(i1 + 1, n)
     for j1 in range(m) for j2 in range(j1 + 1, m)],

    # tag(symmetry-breaking)
    LexIncreasing(x, matrix=True)
)

```

```

minimize(
    Maximum(x)
)

```

After compilation, we have the following additional element in the generated XCSP³ file:

```

<lex class="symmetryBreaking">
    <matrix> x[] [] </matrix>
    <operator> le </operator>
</lex>

```

Note the presence of the attribute `class` that results from the insertion of the expression `tag()`. Easily, a solver can now solve this instance with or without symmetry breaking. Indeed, at time of parsing, it is quite easy to discard XML elements with a specified tag (class): this is currently made possible with the available parsers in Java and C++ for XCSP³. The interest is that we have only one file, which can be used for testing different model variations.

1.2.3 Magic Sequence

A magic sequence of order n is a sequence of integers x_0, \dots, x_{n-1} between 0 and $n - 1$, such that each value $i \in 0..n - 1$ occurs exactly x_i times in the sequence. For example,

```
6 2 1 0 0 0 1 0 0 0
```

is a magic sequence of order 10 since 0 occurs 6 times, 1 occurs twice, ... and 9 occurs 0 times.

One can prove that every solution respects:

$$x_0 + x_1 + x_2 + x_3 + \dots + x_{n-1} = 0$$

and

$$-1x_0 + 0x_1 + 1x_2 + 2x_3 + \dots + (n - 2)x_{n-1} = 0$$

So, it may be a good idea to post these additional constraints and making it clear that they are redundant (i.e., not modifying the set of solutions) by using an appropriate tag. This gives a PyCSP³ model in a file 'MagicSequence.py':

```

PyCSP3 Model 15

from pycsp3 import *

n = data.n

# x[i] is the ith value of the sequence
x = VarArray(size=n, dom=range(n))

satisfy(
    # each value i occurs exactly x[i] times in the sequence
    Cardinality(x, occurrences={i: x[i] for i in range(n)}),

    # tag(redundant-constraints)
    [
        Sum(x) == n,
        Sum((i - 1) * x[i] for i in range(n)) == 0
    ]
)

```

On the one hand, the constraint `cardinality` is exactly what we need here. Here, the PyCSP³ function `Cardinality()` we use simply states that each value i in $0..n - 1$ must occur exactly $x[i]$ times; a named parameter `occurrences` is set to a Python dictionary for storing that information. On the other hand, we have put together the two additional constraints in a list, permitting to tag these two constraints with the token “redundant-constraints”.

Now, if we execute:

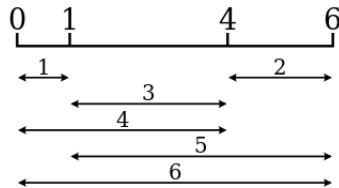

```
python3 MagicSequence.py -data=6
```

we obtain the following XCSP³ instance:

```
<instance format="XCSP3" type="CSP">
<variables>
  <array id="x" note="x[i] is the ith value of the sequence" size="[6]">
    0..5
  </array>
</variables>
<constraints>
  <cardinality note="each value i occurs exactly x[i] times in the sequence">
    <list> x[] </list>
    <values> 0 1 2 3 4 5 </values>
    <occurs> x[] </occurs>
  </cardinality>
  <block class="redundant-constraints">
    <sum>
      <list> x[] </list>
      <condition> (eq,6) </condition>
    </sum>
    <sum>
      <list> x[] </list>
      <coeffs> -1 0 1 2 3 4 </coeffs>
      <condition> (eq,0) </condition>
    </sum>
  </block>
</constraints>
</instance>
```

1.2.4 Golomb Ruler

This problem (and its variants) is said to have many practical applications including sensor placements for x-ray crystallography and radio astronomy. A Golomb ruler is defined as a set of n integers $0 = a_1 < a_2 < \dots < a_n$ such that the $n \times (n - 1)/2$ differences $a_j - a_i$, $1 \leq i < j \leq n$, are distinct. Such a ruler is said to contain n marks (or ticks) and to be of length a_n . The objective is to find optimal rulers (i.e., rulers of minimum length). An optimal ruler for $n = 4$ is illustrated below:

Dimitromanolakis has computed relatively short Golomb rulers and thus showed with computer aid that the optimal ruler for $n \leq 65,000$ has length less than n^2 .

A simple model involves a single constraint `allDifferent`:

PyCSP³ Model 16

```
from pycsp3 import *

n = data.n

# x[i] is the position of the ith tick
x = VarArray(size=n, dom=range(n * n))

satisfy(
    # all distances are different
    AllDifferent(abs(x[i] - x[j]) for i in range(n) for j in range(i + 1, n))
)

minimize(
    # minimizing the position of the rightmost tick
    Maximum(x)
)
```

One model variant involves auxiliary variables and ternary constraints. This variant shows how we can handle holes (“undefined” variables) in variable arrays. This variant is:

PyCSP³ Model 17

```
from pycsp3 import *

n = data.n

# x[i] is the position of the ith tick
x = VarArray(size=n, dom=range(n * n))

def domain_y(i, j):
    return range(1, n * n) if i < j else None

# y[i][j] is the distance between x[i] and x[j] for i strictly less than j
y = VarArray(size=[n, n], dom=domain_y)

satisfy(
    # all distances are different
    AllDifferent(y),

    # linking variables from both arrays
    [x[j] == x[i] + y[i][j] for i in range(n) for j in range(i + 1, n)]
)

minimize(
    # minimizing the position of the rightmost tick
    Maximum(x)
)
```

Here, we declare a two-dimensional array of variables, called y , even if only the part in this array below the main diagonal really contains variables. This is handled by the auxiliary function `domain_y()` that returns an actual domain for a pair (i, j) when $i < j$, and `None` otherwise. This way, we can simply post a constraint `allDifferent` by specifying the array y (even if y contains some “undefined” cells/variables).

Of course, it is possible to use a lambda function when defining domains. Concerning symmetry breaking, we can decide to force $x[0]$ to be equal to 0, and to impose a strict increasing order on variables of x . When we want the values of a sequence of variables to be in increasing or decreasing order, we can call the PyCSP³ functions `Increasing()` or `Decreasing()`; the named parameter `strict` can be used to indicate that the order must be strict. We obtain now:

PyCSP³ Model 18

```
from pycsp3 import *

n = data.n

# x[i] is the position of the ith tick
x = VarArray(size=n, dom=range(n * n))

# y[i][j] is the distance between x[i] and x[j] for i strictly less than j
y = VarArray(size=[n, n], dom=lambda i, j: range(1, n * n) if i < j else None)

satisfy(
    # all distances are different
    AllDifferent(y),

    # linking variables from both arrays
    [x[j] == x[i] + y[i][j] for i in range(n) for j in range(i + 1, n)],

    # tag(symmetry-breaking)
    [x[0] == 0, Increasing(x, strict=True)]
)

minimize(
    # minimizing the position of the rightmost tick
    Maximum(x)
)
```

By executing:

```
python3 GolombRuler.py -data=4
```

we obtain:

```
<instance format="XCSP3" type="COP">
<variables>
    <array id="x" note="x[i] is the position of the ith tick" size="[4]">
        0..16
    </array>
    <array id="y" note="y[i][j] is the distance between x[i] and x[j] for i strictly
        less than j" size="[4][4]">
        1..16
    </array>
</variables>
<constraints>
    <allDifferent note="all distances are different">
        y[0][1..3] y[1][2..3] y[2][3]
    </allDifferent>
    <group note="linking variables from both arrays">
        <intension> eq(%0,add(%1,%2)) </intension>
        <args> x[1] x[0] y[0][1] </args>
        <args> x[2] x[0] y[0][2] </args>
        <args> x[3] x[0] y[0][3] </args>
        <args> x[2] x[1] y[1][2] </args>
        <args> x[3] x[1] y[1][3] </args>
        <args> x[3] x[2] y[2][3] </args>
    </group>
    <block class="symmetry-breaking">
        <intension> eq(x[0],0) </intension>
        <ordered>
            <list> x[] </list>
            <operator> lt </operator>
        </ordered>
    </block>
</constraints>

```

```

</constraints>
<objectives>
  <minimize note="minimizing the position of the rightmost tick" type="maximum">
    x []
  </minimize>
</objectives>
</instance>

```

1.3 Structured Problems

Some problems need more than elementary data, that is more than a few elementary pieces of data such as integers. We call them structured problems.

1.3.1 Sudoku

	4							
5	3	9		1		6		
		1		2		5		
4		7	2		9			6
		6			5			
8			6	3	1		7	
	8		7		2			
6		3			4	1	8	
						7		

(a) Puzzle

2	4	8	5	7	6	9	3	1
5	3	9	4	8	1	7	6	2
6	7	1	9	3	2	8	5	4
4	1	7	2	5	9	3	8	6
3	2	6	8	1	7	5	4	9
8	9	5	6	4	3	1	2	7
1	8	3	7	6	4	2	9	5
7	6	2	3	9	5	4	1	8
9	5	4	1	2	8	6	7	3

(b) Solution

Figure 1.4: Solving a Sudoku Grid

This well-known problem is stated as follows: fill in a grid using digits ranging from 1 to 9 such that:

- all digits occur on each row
- all digits occur on each column
- all digits occur in each 3×3 block (starting at a position multiple of 3)

An illustration is given by Figure 1.4.

Because there are several clues, and because their number cannot be anticipated, we need a parameter `clues` that represents a two-dimensional array of integer values. When `clues[i][j]` is 0, it means that the cell is empty, whereas when it contains a digit between 1 and 9, it means that it represents a fixed value (clue). A PyCSP³ model is given by the following file 'Sudoku.py':

PyCSP³ Model 19

```
from pycsp3 import *

clues = data.clues # if not 0, clues[i][j] is a value imposed at row i and col j

# x[i][j] is the value at row i and col j
x = VarArray(size=[9, 9], dom=range(1, 10))

satisfy(
    # imposing distinct values on each row and each column
    AllDifferent(x, matrix=True),

    # imposing distinct values on each block tag(blocks)
    [AllDifferent(x[i:i + 3, j:j + 3]) for i in [0, 3, 6] for j in [0, 3, 6]],

    # imposing clues tag(clues)
    [x[i][j] == clues[i][j] for i in range(9) for j in range(9)
     if clues and clues[i][j] > 0]
)
```

First, note how the named parameter `matrix` is used to ensure that all digits are different on each row and each column of the two-dimensional array x ; this is the matrix version of `allDifferent`. Second, note how the notation $x[i : i + 3, j : j + 3]$ extracts a list of variables corresponding to a block of size 3×3 in x . This is similar to notations used in package NumPy and in library CPpy. Finally, each clue is naturally imposed under the form of a unary `intension` constraint.

Suppose now that we have a file 'grid.json' containing:

```
{
  "clues": [
    [0, 4, 0, 0, 0, 0, 0, 0, 0],
    [5, 3, 9, 0, 0, 1, 0, 6, 0],
    [0, 0, 1, 0, 0, 2, 0, 5, 0],
    [4, 0, 7, 2, 0, 9, 0, 0, 6],
    [0, 0, 6, 0, 0, 0, 5, 0, 0],
    [8, 0, 0, 6, 0, 3, 1, 0, 7],
    [0, 8, 0, 7, 0, 0, 2, 0, 0],
    [0, 6, 0, 3, 0, 0, 4, 1, 8],
    [0, 0, 0, 0, 0, 0, 0, 7, 0]
  ]
}
```

then, we can execute:

```
python3 Sudoku.py -data=grid.json
```

and we obtain the following XCSP³ instance (simplified here):

```
<instance format="XCSP3" type="CSP">
<variables>
  <array id="x" note="x[i][j] is the value at row i and col j" size="[9][9]">
    1..9
  </array>
</variables>
<constraints>
  <allDifferent note="imposing distinct values on each row and each column">
    <matrix> x[][] </matrix>
  </allDifferent>
  <group note="imposing distinct values on each block" class="blocks">
    <allDifferent> %... </allDifferent>
    <args> x[0..2][0..2] </args>
    <args> x[0..2][3..5] </args>
    <args> x[0..2][6..8] </args>
```

```

<args> x[3..5][0..2] </args>
<args> x[3..5][3..5] </args>
<args> x[3..5][6..8] </args>
<args> x[6..8][0..2] </args>
<args> x[6..8][3..5] </args>
<args> x[6..8][6..8] </args>
</group>
<instantiation note="imposing clues" class="clues">
  <list> x[0][1] x[8][7] </list> // only two of them inserted here for conciseness
  <values> 4 7 </values>
</instantiation>
</constraints>
</instance>

```

Once again, we have used tags. This way, it will be easy at parsing time to discard blocks or clues, if wished. Suppose now that we want to generate an instance without any clue. Of course, we can build a grid only containing the value 0, but this is a little bit tedious. Actually, you just need to use a JSON file like this:

```
{
  "clues": null
}
```

An alternative is simply to execute:

```
python3 Sudoku.py -data=None
```

1.3.2 Warehouse Location

In the Warehouse Location problem (WLP), a company considers opening warehouses at some candidate locations in order to supply its existing stores. Each possible warehouse has the same maintenance cost, and a capacity designating the maximum number of stores that it can supply. Each store must be supplied by exactly one open warehouse. The supply cost to a store depends on the warehouse. The objective is to determine which warehouses to open, and which of these warehouses should supply the various stores, such that the sum of the maintenance and supply costs is minimized. See [CSPLib–Problem 034](#) for more information.

Figure 1.5: Warehouse.

An example of data is the file 'warehouse.json' containing:

```
{
  "fixedCost": 30,
  "warehouseCapacities": [1, 4, 2, 1, 3],
  "storeSupplyCosts": [
    [100, 24, 11, 25, 30], [28, 27, 82, 83, 74],
```

```

        [74, 97, 71, 96, 70], [2, 55, 73, 69, 61],
        [46, 96, 59, 83, 4], [42, 22, 29, 67, 59],
        [1, 5, 73, 59, 56], [10, 73, 13, 43, 96],
        [93, 35, 63, 85, 46], [47, 65, 55, 71, 95]
    ]
}

```

A PyCSP³ model of this problem is given by the following file 'Warehouse.py':

PyCSP³ Model 20

```

from pycsp3 import *

cost = data.fixedCost # for each open warehouse
capacities = data.warehouseCapacities
costs = data.storeSupplyCosts
nWarehouses, nStores = len(capacities), len(costs)

# w[i] is the warehouse supplying the ith store
w = VarArray(size=nStores, dom=range(nWarehouses))

# c[i] is the cost of supplying the ith store
c = VarArray(size=nStores, dom=lambda i: set(costs[i]))

# o[j] is 1 if the jth warehouse is open
o = VarArray(size=nWarehouses, dom={0, 1})

satisfy(
    # capacities of warehouses must not be exceeded
    [Count(w, value=j) <= capacities[j] for j in range(nWarehouses)],

    # the warehouse supplier of the ith store must be open
    [o[w[i]] == 1 for i in range(nStores)],

    # computing the cost of supplying the ith store
    [costs[i][w[i]] == c[i] for i in range(nStores)]
)

minimize(
    # minimizing the overall cost
    Sum(c) + Sum(o) * cost
)

```

Here, we associate a specific domain with each variable of the array c by means of a lambda function. For dealing with warehouse capacities, we use the constraint `count`: the number of variables in a given list (here, w) that take the value specified by the named parameter `value` must be less than a constant. For linking stores with warehouses, we use the constraint `element`: the variable in the array o at index $w[i]$ must be 1 because this variable denotes the warehouse supplying the i th store, and it must be open. Note that the index is not a constant but a variable of our model. Similarly, we use the constraint `element` for computing the actual costs; this time the array contains values (and not variables) and the target to reach is given by a variable. Finally, the objective function corresponds to minimizing two partial sums.

After executing:

```
python3 Warehouse.py -data=warehouse.json
```

we obtain the following XCSP³ instance (some parts are omitted; see the presence of ellipsis):

```
<instance format="XCSP3" type="COP">
<variables>
  <array id="w" note="w[i] is the warehouse supplying the ith store" size="[10]">
```

```

    0..4
</array>
<array id="c" note="c[i] is the cost of supplying the ith store" size="[10]">

</objectives>
</instance>

```

1.3.3 Blackhole

From WikiPedia: “Black Hole is a solitaire card game. Invented by David Parlett, this game’s objective is to compress the entire deck into one foundation. The cards are dealt to a board in piles of three. The leftover card, dealt first or last, is placed as a single foundation called the Black Hole. This card usually is the Ace of Spades. Only the top cards of each pile in the tableau are available for play and in order for a card to be placed in the Black Hole, it must be a rank higher or lower than the top card on the Black Hole. This is the only allowable move in the entire game. The game ends if there are no more top cards that can be moved to the Black Hole. The game is won if all of the cards end up in the Black Hole.” An illustration is given by Figure 1.6.

We may want to play with various sizes of piles and various number of cards per suit. An example of data is given by the file ‘blackhole.json’ containing:

```
{
```

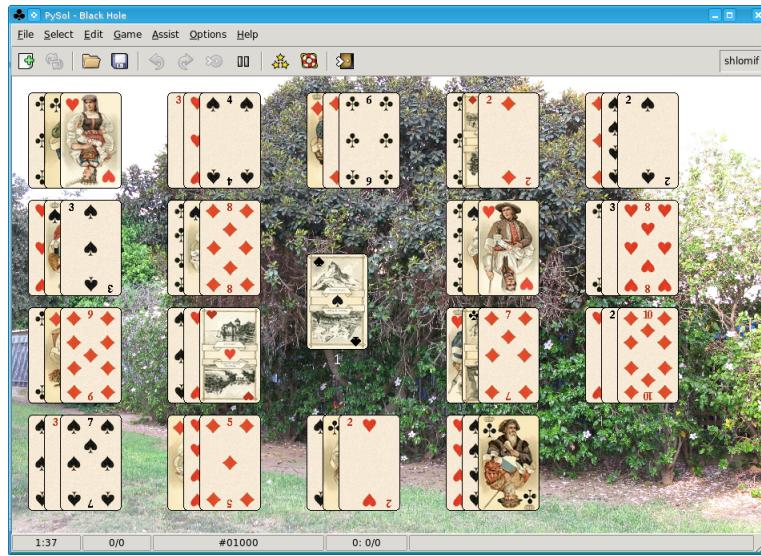

Figure 1.6: Blackhole.

```
"nCardsPerSuit": 4,
"piles": [[1, 4, 13], [15, 9, 6], [14, 2, 12], [7, 8, 5], [11, 10, 3]]}
```

A PyCSP³ model of this problem is given by the following file 'Blackhole.py':

 **PyCSP³ Model 21**

```
from pycsp3 import *

m, piles = data.nCardsPerSuit, data.piles
nCards = 4 * m

# x[i] is the value j of the card at position i of the stack
x = VarArray(size=nCards, dom=range(nCards))

# y[j] is the position i of the card whose value is j
y = VarArray(size=nCards, dom=range(nCards))

table = {(i, j) for i in range(nCards) for j in range(nCards)
          if i % m == (j + 1) % m or j % m == (i + 1) % m}

satisfy(
    Channel(x, y),

    # the Ace of Spades is initially put on the stack
    y[0] == 0,

    # cards must be played in the order of the piles
    Increasing([y[j] for j in pile], strict=True) for pile in piles,

    # each new card put on the stack must be at a higher or lower rank
    [(x[i], x[i + 1]) in table for i in range(nCards - 1)])
)
```

Note how the `channel` constraint is used to make a channeling between the two arrays x and y , how

the value of the first variable of y is imposed by a unary `intension` constraint, how we guarantee to take cards from each pile in a strict increasing order with `increasing` constraints and how `extension` constraints are posted after having precomputed a table.

Because the same table constraint is imposed on successive pairs of variables, we can use the meta-constraint `slide`, which may be useful to solvers. It suffices to replace the last argument of `satisfy()` with:

```
Slide((x[i], x[i + 1]) in table for i in range(nCards - 1))
```

With this meta-constraint `slide`, after executing:

```
python3 Blackhole.py -data=blackhole.json
```

we obtain the following XCSP³ instance:

```
<instance format="XCSP3" type="CSP">
<variables>
  <array id="x" note="x[i] is the value j of the card at position i of the stack"
    size="[16]">
    0..15
  </array>
  <array id="y" note="y[j] is the position i of the card whose value is j" size="
    [16]">
    0..15
  </array>
</variables>
<constraints>
  <channel>
    <list> x[] </list>
    <list> y[] </list>
  </channel>
  <intension note="the Ace of Spades is initially put on the stack"> eq(y[0],0) </
    intension>
  <group note="cards must be played in the order of the piles">
    <ordered>
      <list> %0 %1 %2 </list>
      <operator> lt </operator>
    </ordered>
    <args> y[1] y[4] y[13] </args>
    <args> y[15] y[9] y[6] </args>
    <args> y[14] y[2] y[12] </args>
    <args> y[7..8] y[5] </args>
    <args> y[11] y[10] y[3] </args>
  </group>
  <slide note="each new card put on the stack must be at a higher or lower rank">
    <list> x[] </list>
    <extension>
      <list> %0 %1 </list>
      <supports> (0,1)(0,3)(0,5)(0,7)(0,9)(0,11)(0,13)(0,15)(1,0)(1,2)(1,4)(1,6)
        (1,8)(1,10)(1,12)(1,14)(2,1)(2,3)(2,5)(2,7)(2,9)(2,11)(2,13)(2,15)(3,0)
        (3,2)(3,4)(3,6)(3,8)(3,10)(3,12)(3,14)(4,1)(4,3)(4,5)(4,7)(4,9)(4,11)
        (4,13)(4,15)(5,0)(5,2)(5,4)(5,6)(5,8)(5,10)(5,12)(5,14)(6,1)(6,3)(6,5)
        (6,7)(6,9)(6,11)(6,13)(6,15)(7,0)(7,2)(7,4)(7,6)(7,8)(7,10)(7,12)(7,14)
        (8,1)(8,3)(8,5)(8,7)(8,9)(8,11)(8,13)(8,15)(9,0)(9,2)(9,4)(9,6)(9,8)(9,10)
        (9,12)(9,14)(10,1)(10,3)(10,5)(10,7)(10,9)(10,11)(10,13)(10,15)(11,0)
        (11,2)(11,4)(11,6)(11,8)(11,10)(11,12)(11,14)(12,1)(12,3)(12,5)(12,7)
        (12,9)(12,11)(12,13)(12,15)(13,0)(13,2)(13,4)(13,6)(13,8)(13,10)(13,12)
        (13,14)(14,1)(14,3)(14,5)(14,7)(14,9)(14,11)(14,13)(14,15)(15,0)(15,2)
        (15,4)(15,6)(15,8)(15,10)(15,12)(15,14) </supports>
    </extension>
  </slide>
</constraints>
</instance>
```

1.3.4 Rack Configuration

Figure 1.7: Rack.

The rack configuration problem consists of plugging a set of electronic cards into racks with electronic connectors. Each card plugged into a rack uses a connector. In order to plug a card into a rack, the rack must be of a rack model. Each card is characterized by the power it requires. Each rack model is characterized by the maximal power it can supply, its size (number of connectors), and its price. The problem is to decide how many of the available racks are actually needed such that:

- every card is plugged into one rack
- the total power demand and the number of connectors required by the cards does not exceed that available for a rack
- the total price is minimized.

See [CSPLib–Problem 031](#) for more information.

An example of data is given by the file 'rack.json' containing:

```
{
  "nRacks": 10,
  "models": [[150, 8, 150], [200, 16, 200]],
  "cardTypes": [[20, 20], [40, 8], [50, 4], [75, 2]]
}
```

A PyCSP³ model for this problem is given by the following file 'Rack.py':

PyCSP³ Model 22

```
from pycsp3 import *

nRacks, models, cardTypes = data.nRacks, data.models, data.cardTypes

# we add first a dummy model (0,0,0)
models = [(0, 0, 0)] + [tuple(model) for model in models]
nModels, nTypes = len(models), len(cardTypes)

powers = [row[0] for row in models]
sizes = [row[1] for row in models]
costs = [row[2] for row in models]
cardPowers = [row[0] for row in cardTypes]
cardDemands = [row[1] for row in cardTypes]

# m[i] is the model used for the ith rack
m = VarArray(size=nRacks, dom=range(nModels))
```

```

# nc[i][j] is the number of cards of type j put in the ith rack
nc = VarArray(size=[nRacks, nTypes],
              dom=lambda i, j: range(min(max(sizes), cardDemands[j]) + 1))

# p[i] is the power of the ith rack
p = VarArray(size=nRacks, dom=set(powers))

# s[i] is the size of the ith rack
s = VarArray(size=nRacks, dom=set(sizes))

# c[i] is the cost of the ith rack
c = VarArray(size=nRacks, dom=set(costs))

satisfy(
    # linking model and power of the ith rack
    [(m[i], p[i]) in enumerate(powers) for i in range(nRacks)],

    # linking model and size of the ith rack
    [(m[i], s[i]) in enumerate(sizes) for i in range(nRacks)],

    # linking model and cost of the ith rack
    [(m[i], c[i]) in enumerate(costs) for i in range(nRacks)],

    # connector-capacity constraints
    [Sum(nc[i]) <= s[i] for i in range(nRacks)],

    # power-capacity constraints
    [nc[i] * cardPowers <= p[i] for i in range(nRacks)],

    # demand constraints
    [Sum(nc[:, j]) == cardDemands[j] for j in range(nTypes)],

    # tag(symmetry-breaking)
    [
        Decreasing(m),
        (m[0] != m[1]) | (nc[0][0] >= nc[1][0])
    ]
)

minimize(
    # minimizing the total cost paid for all racks
    Sum(c)
)

```

After initially building some useful lists, five arrays of variables are declared. Then, three lists of **extension** constraints are posted. Note how the Python function `enumerate()` allows us to build tables that are relevant for our model. Then, three lists of **sum** constraints are posted. In the second list, we use a dot product, and in the third list, we use the notation $nc[:, j]$ to extract the j th column of the array nc , as in NumPy.

Concerning the function `enumerate()` called in the context of an **extension** constraint, the returned object is automatically transformed into a set.

```

>>> t = [2, 3, 4]
>>> enumerate(t)
<enumerate object at 0x7f42c5148708>
>>> set(enumerate(t))
{(0, 2), (1, 3), (2, 4)}

```

As usual, for generating an XCSP³ instance, we just need to execute:

```
python3 Rack.py -data=rack.json
```

One drawback with the previous model is that it is difficult to understand the role of each piece of data, when looking independently at the JSON file. One remedy is then to choose a clearer structure as in this file 'rack2.json':

```
{
  "nRacks": 10,
  "rackModels": [
    {"power": 150, "nConnectors": 8, "price": 150},
    {"power": 200, "nConnectors": 16, "price": 200}
  ],
  "cardTypes": [
    {"power": 20, "demand": 20},
    {"power": 40, "demand": 8},
    {"power": 50, "demand": 4},
    {"power": 75, "demand": 2}
  ]
}
```

In PyCSP³, it is quite easy to change the representation (structure) of data. It suffices to update the way the predefined PyCSP³ object `data` is used in the model. In our case, with this new representation, we modify the first part of our file 'Rack.py' as follows:

PyCSP³ Model 23

```
from pycsp3 import *

nRacks, models, cardTypes = data.nRacks, data.rackModels, data.cardTypes

# we add first a dummy model (0,0,0)
models = [{'power': 0, 'nConnectors': 0, 'price': 0}] + models
nModels, nTypes = len(models), len(cardTypes)

powers = [model['power'] for model in models]
sizes = [model['nConnectors'] for model in models]
costs = [model['price'] for model in models]
cardPowers = [cardType['power'] for cardType in cardTypes]
cardDemands = [cardType['demand'] for cardType in cardTypes]

... # the rest of the model remains the same
```

Again we add a dummy rack model to those defined in the JSON file. Note that the fact of adding a new dictionary to `models` breaks the homogeneity of the list. The list `models` contains now a first element of type 'dict' followed by elements of type 'DataDict', as explained later at Page 37. This means that we need square bracket notation to get values associated with keys. However, it is possible to build an object 'DataDict' and use dot notation, as shown below:

```
from pycsp3 import *

nRacks, models, cardTypes = data.nRacks, data.rackModels, data.cardTypes

# we add first a dummy model (0,0,0)
models = [DataDict({'power': 0, 'nConnectors': 0, 'price': 0})] + models
nModels, nTypes = len(models), len(cardTypes)

powers = [model.power for model in models]
sizes = [model.nConnectors for model in models]
costs = [model.price for model in models]
cardPowers = [cardType.power for cardType in cardTypes]
cardDemands = [cardType.demand for cardType in cardTypes]

... # the rest of the model remains the same
```

Chapter 2

Data, Variables and Objectives

In this chapter, we give some additional details and illustrations about data, variables and objectives, although many examples can be found in the other chapters.

2.1 Specifying Data

Except for “single” problems, each problem usually represents a large (often, infinite) family of cases, called instances, that one may want to solve. All these instances are uniquely identified by some specific data.

First, recall that the command to be run for generating an XCSP³ instance (file), given a model and some data is:

```
python3 <model_file> -data=<data_values>
```

where `<model_file>` (is a Python file that) represents a PyCSP³ model, and `<data_values>` represents some specific data. In our context, an *elementary* value is a value of one of these built-in data types: integer ('int'), real ('float'), string ('str') and boolean ('bool'). Specific data can be given as:

1. a single elementary value, as in `-data=5`
2. a list of elementary values, as in `-data=[9,0,0,3,9]`
3. a list of named elementary values, as in `-data=[v=9,b=0,r=0,k=3,l=9]`
4. a JSON file, as in `-data=Bibd-9-3-9.json`
5. a file in any arbitrary format (e.g., a text file) while providing with the option `-dataparser` some Python code to load it, as in `-data=puzzle.txt -dataparser=ParserPuzzle.py`

Then, **data can be directly used in PyCSP³ models by means of a predefined object called `data`.**

Although various cases have already been illustrated in Chapter 1, we introduce below a few additional examples.

All-Interval Series. Given the twelve standard pitch-classes ($c, c\#, d, \dots$), represented by numbers $0, 1, \dots, 11$, find a series in which each pitch-class occurs exactly once and in which the musical intervals between neighboring notes cover the full set of intervals from the minor second (1 semitone) to the major seventh (11 semitones). That is, for each of the intervals, there is a pair of neighboring pitch-classes in the series, between which this interval appears.

Elliott Carter often bases his all-interval sets on the list generated by Bauer-Mendelberg and Ferentz and uses them as a "tonic" sonority (image from commons.wikimedia.org)

The problem of finding such a series can be easily formulated as an instance of a more general arithmetic problem. Given a positive integer n , find a sequence $x = \langle x_0, x_1, \dots, x_{n-1} \rangle$, such that:

1. x is a permutation of $\{0, 1, \dots, n - 1\}$;
2. the interval sequence $y = \langle |x_1 - x_0|, |x_2 - x_1|, \dots, |x_{n-1} - x_{n-2}| \rangle$ is a permutation of $\{1, 2, \dots, n - 1\}$.

A sequence satisfying these conditions is called an all-interval series of order n ; the problem of finding such a series is the all-interval series problem of order n . For example, for $n = 8$, a solution is:

1 7 0 5 4 2 6 3

A PyCSP³ model of this problem is given by the following file 'AllInterval.py':

PyCSP³ Model 24

```
from pycsp3 import *

n = data.n

# x[i] is the ith note of the series
x = VarArray(size=n, dom=range(n))

satisfy(
    # notes must occur once, and so form a permutation
    AllDifferent(x),

    # intervals between neighbouring notes must form a permutation
    AllDifferent(abs(x[i] - x[i + 1])) for i in range(n - 1),
)
```

Here, the required data is a single integer value. So, to generate the XCSP³ instance of AllInterval for order 12, we just execute:

```
python3 AllInterval.py -data=12
```

Balanced Incomplete Block Designs. From [CSPLib](#): "Balanced Incomplete Block Design (BIBD) generation is a standard combinatorial problem from design theory, originally used in the design of statistical experiments but since finding other applications such as cryptography. It is a special case of Block Design, which also includes Latin Square problems. BIBD generation is described in most standard textbooks on combinatorics. A BIBD is defined as an arrangement of v distinct objects into b blocks such that each block contains exactly k distinct objects, each object occurs in exactly r different blocks, and every two distinct objects occur together in exactly λ blocks. Another way of defining a BIBD is in terms of its incidence matrix, which is a v by b binary matrix with exactly r

ones per row, k ones per column, and with a scalar product of λ between any pair of distinct rows. A BIBD is therefore specified by its parameters (v, b, r, k, λ) .

Hence, we need five integers v, b, r, k, lmb (for λ) for specifying a unique instance; possibly, b and r can be set to 0, so that these values are automatically computed according to a classical BIBD template. A PyCSP³ model of this problem is given by the following file 'Bibd.py':

PyCSP³ Model 25

```
from pycsp3 import *

v, b, r, k, lmb = data.v, data.b, data.r, data.k, data.lmb
b = (lmb * v * (v - 1)) // (k * (k - 1)) if b == 0 else b
r = (lmb * (v - 1)) // (k - 1) if r == 0 else r

# x[i][j] is the value of the matrix at row i and column j
x = VarArray(size=[v, b], dom={0, 1})

satisfy(
    # constraints on rows
    [Sum(row) == r for row in x],

    # constraints on columns
    [Sum(col) == k for col in columns(x)],

    # scalar constraints with respect to lambda
    [row1 * row2 == lmb for (row1, row2) in combinations(x, 2)]
)
```

To generate an XCSP³ instance (file), we can for example execute:

```
python3 Bibd.py -data=[9,0,0,3,9]
```

With some command interpreters (shells), you may have to escape the characters '[' and ']', which gives:

```
python3 Bibd.py -data=\[9,0,0,3,9\]
```

It is important to note how values are associated with fields of the PyCSP³ object `data`. Actually, the order of occurrences of these fields in the model is automatically used. The first occurrence of a field of `data` is `data.v`, then it is `data.b`, and so on. So, we have `data.v=9`, `data.b=0`, ...

However, you can relax this requirement by using names when specifying data, as for example:

```
python3 Bibd.py -data=[k=3,lmb=9,b=0,r=0,v=9]
```

Suppose that you would prefer to have a JSON file for storing these data values. You can execute:

```
python3 Bibd.py -data=[9,0,0,3,9] -datelexport
```

You then obtain the following JSON file 'Bibd-9-0-0-3-9.json'

```
{
    "v": 9,
    "b": 0,
    "r": 0,
    "k": 3,
    "lmb": 9
}
```

And now, to generate the same XCSP³ instance (file) as above, you can execute:

```
python3 Bibd.py -data=Bibd-9-0-0-3-9.json
```

Balanced Academic Curriculum Problem (BACP). From [CSPLib](#): “The goal of BACP is to design a balanced academic curriculum by assigning periods to courses in a way that the academic load of each period is balanced, i.e., as similar as possible. An academic curriculum is defined by a set of courses and a set of prerequisite relationships among them. Courses must be assigned within a maximum number of academic periods. Each course is associated to a number of credits or units that represent the academic effort required to successfully follow it.

The curriculum must obey the following regulations:

- minimum academic load: a minimum number of academic credits per period is required to consider a student as full time
- maximum academic load: a maximum number of academic credits per period is allowed in order to avoid overload
- minimum number of courses: a minimum number of courses per period is required to consider a student as full time
- maximum number of courses: a maximum number of courses per period is allowed in order to avoid overload

The goal is to assign a period to every course in a way that the minimum and maximum academic load for each period, the minimum and maximum number of courses for each period, and the prerequisite relationships are satisfied. An optimal balanced curriculum minimizes the maximum academic load for all periods.”

When analyzing this problem, we identify its parameters as being the number of periods (an integer), the minimum and the maximum number of credits (two integers), the minimum and the maximum number of courses (two integers), the credits for each course (a one-dimensional array of integers) and the prerequisites (a two-dimensional array of integers, with each row indicating a prerequisite). An example of data is given by the following JSON file:

```
{
  "nPeriods": 4,
  "minCredits": 2,
  "maxCredits": 5,
  "minCourses": 2,
  "maxCourses": 3,
  "credits": [2, 3, 1, 3, 2, 3, 3, 2, 1],
  "prerequisites": [[2, 0], [4, 1], [5, 2], [6, 4]]
}
```

A PyCSP³ model of this problem is given by the following file 'Bacp.py':

PyCSP³ Model 26

```
from pycsp3 import *

nPeriods = data.nPeriods
minCredits, maxCredits = data.minCredits, data.maxCredits
minCourses, maxCourses = data.minCourses, data.maxCourses
credits, prerequisites = data.credits, data.prerequisites
nCourses, nPrerequisites = len(credits), len(prerequisites)
```

```

def table(c):
    return {tuple(credits[c] if j == p else p if j == nPeriods else 0
                 for j in range(nPeriods + 1)) for p in range(nPeriods)}

# s[c] is the period (schedule) for course c
s = VarArray(size=nCourses, dom=range(nPeriods))

# co[p] is the number of courses at period p
co = VarArray(size=nPeriods, dom=range(minCourses, maxCourses + 1))

# cr[p] is the number of credits at period p
cr = VarArray(size=nPeriods, dom=range(minCredits, maxCredits + 1))

# cp[c][p] is 0 if the course c is not planned at period p
#           the number of credits for c otherwise
cp = VarArray(size=[nCourses, nPeriods], dom=lambda c, p: {0, credits[c]})

satisfy(
    # channeling between arrays cp and s
    [(*cp[c], s[c]) in table(c) for c in range(nCourses)],

    # counting the number of courses in each period
    [Count(s, value=p) == co[p] for p in range(nPeriods)],

    # counting the number of credits in each period
    [Sum(cp[:, p]) == cr[p] for p in range(nPeriods)],

    # handling prerequisites
    [s[c1] < s[c2] for (c1, c2) in prerequisites]
)

minimize(
    # minimizing the maximum number of credits in periods
    Maximum(cr)
)

```

It is important to note that the fields of the main object in the JSON file can be given in any order. This means that the JSON file given above is operationally equivalent to this one:

```
{
  "nPeriods": 4,
  "prerequisites": [[2,0],[4,1],[5,2],[6,4]],
  "minCredits": 2,
  "maxCredits": 5,
  "credits": [2,3,1,3,2,3,3,2,1],
  "minCourses": 2,
  "maxCourses": 3
}
```

Now, let us suppose that you would like to use the data from this MiniZinc file 'bacp-data.mzn':

```

include "curriculum.mzn.model";
n_courses = 9;
n_periods = 4;
load_per_period_lb = 2;
load_per_period_ub = 5;
courses_per_period_lb = 2;
courses_per_period_ub = 3;
course_load = [2, 3, 1, 3, 2, 3, 3, 2, 1, ];
constraint prerequisite(2, 0);
constraint prerequisite(4, 1);
constraint prerequisite(5, 2);
constraint prerequisite(6, 4);

```

We need to write a piece of code in Python for building the object `data` that will be used in our model. After importing everything (*) from `pycsp3.problems.data.dataparser`, we can use some PyCSP³ functions such as `next_line()`, `number_in()`, `remaining_lines()`, ... Here, we also use the classical function `split()` of module `re` to parse information concerning prerequisites. Note how we can add any new arbitrary field to the object `data` in the following file 'Bacp_ParserZ.py':

```
from pycsp3.problems.data.dataparser import *

data.nCourses = number_in(next_line())
data.nPeriods = number_in(next_line())
data.minCredits = number_in(next_line())
data.maxCredits = number_in(next_line())
data.minCourses = number_in(next_line())
data.maxCourses = number_in(next_line())
data.credits = numbers_in(next_line())
data.prerequisites = [[int(v) - 1
    for v in re.split(r'constraint prerequisite\(|,\|; ', line) if len(v) > 0]
    for line in remaining_lines(skip_curr=True)]
```

To generate the XCSP³ instance (file), you have to execute:

```
python3 Bacp.py -data=bacp.mzn -dataparser=Bacp_ParserZ.py
```

If you want the same data put in a JSON file, execute:

```
python3 Bacp.py -data=bacp-data.mzn -dataparser=Bacp_ParserZ.py -dataexport
```

You obtain a file called 'bacp-data.json' equivalent to those introduced earlier. If you want to specify the name of the output JSON file, give it as a value to the option `-dataexport`, as e.g., in:

```
python3 Bacp.py -data=bacp-data.mzn -dataparser=Bacp_ParserZ.py -dataexport=instance0
```

The generated JSON file is then called 'instance0.json'.

Special Types for Lists and Dictionaries occurring in the Object `data`. Any time, you get from a JSON file, a field `f` of the object `data` such that:

1. `f` is a list (or recursively, a list of lists) containing only integers, the type of `data.f` is '`pycsp3.tools.curser.ListInt`' instead of 'list'; 'ListInt' being a subclass of 'list'. The main interest is that `data.f` can be directly used as a vector for the global constraint `element`. See Mario Problem, page 75, for an illustration.
2. `f` is an object, the type of `data.f` is '`pycsp3.problems.data.dataparser.DataDict`' instead of 'dict'; 'DataDict' being a subclass of 'dict'. The main interest is that any key `k` of `data.f` can be accessed with dot notation (`data.f.k`) and not only with square bracket notation (`data.f['k']`). See Rack Configuration Problem in Section 1.3.4 for an illustration.

Of course, the type of the object `data` is 'DataDict', which explains why we can use dot notation to get access to its different fields (parameters).

Finally, when we define a list (array) `x` of variables with `VarArray()`, the type of `x` is '`pycsp3.tools.curser.ListVar`' instead of 'list'. The main interest is that `x` can be directly used as a vector for the global constraint `element`.

Special Values `null` and `None`. When the value `null` occurs in a JSON file, it becomes `None` in PyCSP³ after loading the data file. An illustration is given at the end of Section 1.3.1.

2.2 Declaring Variables

2.2.1 Stand-alone Variables

Stand-alone variables can be declared by means of the PyCSP³ function `Var()`. To define the domain of a variable, we can simply list values, or use `range()`. For example:

```
w = Var(range(15))
x = Var(0, 1)
y = Var(0, 2, 4, 6, 8)
z = Var("a", "b", "c")
```

declares four variables corresponding to:

- o $w \in \{0, 1, \dots, 14\}$
- o $x \in \{0, 1\}$
- o $y \in \{0, 2, 4, 6, 8\}$
- o $z \in \{"a", "b", "c"\}$

Values can be directly listed as above, or given in a set as follows:

```
w = Var(set(range(15)))
x = Var({0, 1})
y = Var({0, 2, 4, 6, 8})
z = Var({"a", "b", "c"})
```

It is also possible to name the parameter `dom` when defining the domain:

```
w = Var(dom=range(15))    # or equivalently, w = Var(dom=set(range(15)))
x = Var(dom={0, 1})
y = Var(dom={0, 2, 4, 6, 8})
z = Var(dom={"a", "b", "c"})
```

Finally, it is of course possible to use comprehension lists. For example, for y , we can write:

```
y = Var(i for i in range(10) if i % 2 == 0)
```

or equivalently:

```
y = Var({i for i in range(10) if i % 2 == 0})
```

or equivalently:

```
y = Var(dom={i for i in range(10) if i % 2 == 0})
```

Remark 4 Currently in PyCSP³, we can only define integer and symbolic variables, i.e., variables with a finite set of integers or symbols (strings).

2.2.2 Arrays of Variables

The PyCSP³ function for declaring an array of variables is `VarArray()` that requires two named parameters `size` and `dom`. For declaring a one-dimensional array of variables, the value of `size` must be an integer (or a list containing only one integer), for declaring a two-dimensional array of variables, the value of `size` must be a list containing exactly two integers, and so on. The named parameter `dom` indicates the domain of each variable in the array.

The signature of the function `VarArray()` is:

```
def VarArray(*, size, dom):
```

An illustration is given by:

```
x = VarArray(size=10, dom={0, 1})
y = VarArray(size=[5, 20], dom=range(10))
z = VarArray(size=[4, 3, 4], dom={1, 5, 10, 20})
```

We have:

- o x , a one-dimensional array of 10 variables with domain $\{0, 1\}$
- o y , a two-dimensional array of 5×20 variables with domain $\{0, 1, \dots, 9\}$
- o z , a three-dimensional array of $4 \times 3 \times 4$ variables with domain $\{1, 5, 10, 20\}$

Indexing starts at 0. For example, $x[2]$ is the third variable of x , and $y[1]$ is the second row of y . Technically, variable arrays are objects that are instances of `ListVar`, a subclass of `list`; additional functionalities of such objects are useful, for example, when posting the `element` constraint.

In some situations, you may want to declare variables in an array with different domains. For a one-dimensional array, you can give the name of a function that accepts an integer i and returns the domain to be associated with the variable at index i in the array. For a two-dimensional array, you can give the name of a function that accepts a pair of integers (i, j) and returns the domain to be associated with the variable at indexes i, j in the array. And so on.

For example, suppose that the domain of all variables of the first column of y is `range(5)` instead of `range(10)`. We can write:

```
def domain_y(i,j):
    return range(5) if j == 0 else range(10)

y = VarArray(size=[5, 20], dom=domain_y)
```

We can also use a lambda function:

```
y = VarArray(size=[5, 20], dom=lambda i,j: range(5) if j == 0 else range(10))
```

Sometimes, not all variables in an array are relevant. For example, you may only want to use the variables in the lower part of a two-dimensional array (matrix). In that case, the value `None` must be used. An illustration is given below:

Golomb Ruler. This problem was introduced in Section 1.2.4. Here is a snippet of the PyCSP³ model:

```
# y[i][j] is the distance between x[i] and x[j] for i strictly less than j
y = VarArray(size=[n, n], dom=lambda i, j: range(1, n * n) if i < j else None)
```

In the array y , the upper part (above the main downward diagonal) only contains `None`. For example, $y[1][0]$ is equal to `None`. This is taken into consideration when constraints are posted.

Sometimes, one may want to be able to refer to variables in arrays in an individual manner. It suffices to use facilities offered by Python.

Allergy. Four friends (two women named Debra and Janet, and two men named Hugh and Rick) found that each of them is allergic to something different: eggs, mold, nuts and ragweed. We would like to match each one's surname (Baxter, Lemon, Malone and Fleet) with his or her allergy. We know that:

- o Rick isn't allergic to mold
- o Baxter is allergic to eggs
- o Hugh isn't surnamed Lemon or Fleet
- o Debra is allergic to ragweed
- o Janet (who isn't Lemon) isn't allergic to eggs or mold

A PyCSP³ model of this problem is given by the following file 'Allergy.py':

PyCSP³ Model 27

```
from pycsp3 import *

Debra, Janet, Hugh, Rick = friends = ["Debra", "Janet", "Hugh", "Rick"]

# foods[i] is the friend allergic to the ith food
eggs, mold, nuts, ragweed = foods = VarArray(size=4, dom=friends)

# surnames[i] is the friend with the ith surname
baxter, lemon, malone, fleet = surnames = VarArray(size=4, dom=friends)

satisfy(
    AllDifferent(foods),
    AllDifferent(surnames),

    mold != Rick,
    eggs == baxter,
    lemon != Hugh,
    fleet != Hugh,
    ragweed == Debra,
    lemon != Janet,
    eggs != Janet,
    mold != Janet
)
```

Any comment put in the line preceding the declaration of a variable (or variable array) is automatically inserted in the XCSP³ file, except for cases where individual variables and arrays are declared on the same line, as in the model above.

2.3 Specifying Objectives

For specifying an objective to optimize, you must call one of the two functions:

```
def minimize(term):
```

```
def maximize(term):
```

The argument `term` can be:

- o a variable, as in `minimize(v)`
- o an expression, as in `minimize(v + w * w)`
- o a sum, as in `minimize(Sum(x))`
- o a dot product, as in `minimize([u,v,w] * [3, 2, 5])`
- o a generator, as in `minimize(Sum((x[i] > 1) * c[i] for i in range(n)))`
- o a minimum, as in `minimize(Minimum(x))`
- o a maximum, as in `minimize(Maximum(x))`
- o a number of distinct values, as in `minimize(NValues(x))`
- o ...

Chapter 3

Twenty Popular Constraints

In this chapter, we introduce some popular constraints, those recognized by many constraint solvers (and from XCSP³-core). Figure 3.1 shows their classification. The description of the meta-constraint `slide` is currently missing (but is planned to be totally written by mid-January 2010).

Semantics. Concerning the semantics, here are a few important remarks:

- when presenting the semantics, we distinguish between a variable x and its assigned value \mathbf{x} (note the bold face on the symbol x).
- in many constraints, quite often, we need to introduce numerical conditions (comparisons) composed of an operator \odot in $\{<, \leq, >, \geq, =, \neq, \in, \notin\}$ and a right-hand side operand k that can be a value (constant), a variable of the model, an interval or a set; the left-hand side being indirectly defined by the constraint. The numerical condition is a kind of terminal operation to be applied after the constraint has “performed some computation”. In Python, the operator \odot is from $\{<, \leq, >, \geq, ==, !=, \text{in}, \text{not in}\}$ and an interval is given by a `range` object. For example, constraints involving numerical conditions are `Sum(x) > 10`, `Count(x, value = 1) in range(10)`, `NValues(x) in {2, 4, 6}` and `Minimum(x) == y`. Of course, we can also write $10 < \text{Sum}(x)$ and $y == \text{Minimum}(x)$, but for simplicity of the presentation, we shall always assume that numerical conditions are on the right side. For the semantics of a numerical condition (\odot, k) , and depending on the form of k (a value, a variable, an interval or a set), we shall indiscriminately use \mathbf{k} to denote the value of the constant k , the value of the variable k , the interval $l..u$ represented by k , or the set $\{a_1, \dots, a_p\}$ represented by k .

3.1 Constraint intension

An **intension** constraint corresponds to a Boolean expression, which is usually called predicate. For example, the constraint $x+y = z$ corresponds to an equation, which is an expression evaluated to *false* or *true* according to the values assigned to the variables x , y and z . However, note that for equality, we need to use `==` in Python (the operator `=` used for assignment cannot be redefined), and so, the previous constraint must be written $x+y == z$ in PyCSP³. To build predicates, classical arithmetic, relational and logical operators (and functions) are available; they are presented in Table 1.1 and Table 1.2. In Table 1.3, you can find a few examples of **intension** constraints. Note that the integer values 0 and 1 are respectively equivalent to the Boolean values *false* and *true*. This allows us to combine Boolean expressions with arithmetic operators (for example, addition) without requiring any type conversions. For example, it is valid to write $(x < 5) + (y < z) == 1$ for stating that exactly one of the Boolean expressions $x < 5$ and $y < z$ must be true, although it may be possible (and more relevant) to write it differently.

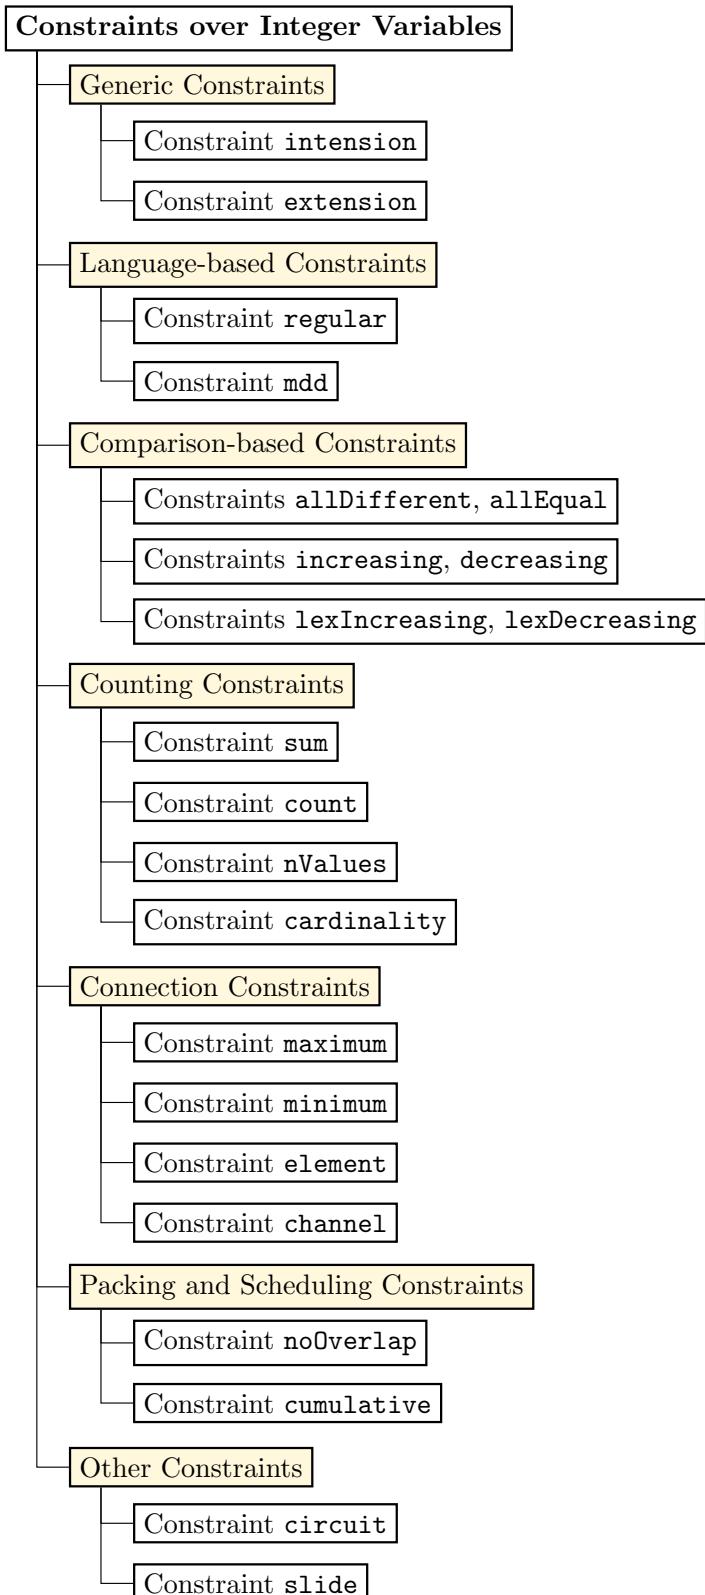

Figure 3.1: Popular constraints over integer variables.

Below, P denotes a predicate expression with r formal parameters (not shown here, for simplicity), $X = \langle x_0, x_1, \dots, x_{r-1} \rangle$ denotes a sequence of r variables, the scope of the constraint, and $P(\mathbf{x}_0, \mathbf{x}_1, \dots, \mathbf{x}_{r-1})$ denotes the value (0/false or 1/true) returned by P for a specific instantiation of the variables of X .

Semantics 1

```
intension( $X, P$ ), with  $X = \langle x_0, x_1, \dots, x_{r-1} \rangle$  and  $P$  a predicate iff
 $P(\mathbf{x}_0, \mathbf{x}_1, \dots, \mathbf{x}_{r-1}) = \text{true}$  (1) // recall that 1 is equivalent to true
```

Zebra. The Zebra puzzle (sometimes referred to as Einstein's puzzle) is defined as follows. There are five houses in a row, numbered from left to right. Each of the five houses is painted a different color, and has one inhabitant. The inhabitants are all of different nationalities, own different pets, drink different beverages and have different jobs.

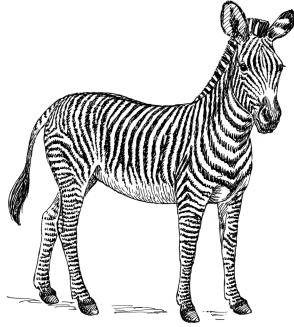

Figure 3.2: In which house lives the zebra?

We know that:

- o colors are yellow, green, red, white, and blue
- o nations of inhabitants are italy, spain, japan, england, and norway
- o pets are cat, zebra, bear, snails, and horse
- o drinks are milk, water, tea, coffee, and juice
- o jobs are painter, sculptor, diplomat, pianist, and doctor
- o The painter owns the horse
- o The diplomat drinks coffee
- o The one who drinks milk lives in the white house
- o The Spaniard is a painter
- o The Englishman lives in the red house
- o The snails are owned by the sculptor
- o The green house is on the left of the red one
- o The Norwegian lives on the right of the blue house
- o The doctor drinks milk
- o The diplomat is Japanese

- o The Norwegian owns the zebra
- o The green house is next to the white one
- o The horse is owned by the neighbor of the diplomat
- o The Italian either lives in the red, white or green house

A PyCSP³ model of this problem is given by the following file 'Zebra.py':

PyCSP³ Model 28

```
from pycsp3 import *

# colors[i] is the house of the ith color
yellow, green, red, white, blue = colors = VarArray(size=5, dom=range(5))

# nations[i] is the house of the inhabitant with the ith nationality
italy, spain, japan, england, norway = nations = VarArray(size=5, dom=range(5))

# jobs[i] is the house of the inhabitant with the ith job
painter, sculptor, diplomat, pianist, doctor = jobs = VarArray(size=5, dom=range(5))

# pets[i] is the house of the inhabitant with the ith pet
cat, zebra, bear, snails, horse = pets = VarArray(size=5, dom=range(5))

# drinks[i] is the house of the inhabitant with the ith preferred drink
milk, water, tea, coffee, juice = drinks = VarArray(size=5, dom=range(5))

satisfy(
    AllDifferent(colors),
    AllDifferent(nations),
    AllDifferent(jobs),
    AllDifferent(pets),
    AllDifferent(drinks),

    painter == horse,
    diplomat == coffee,
    white == milk,
    spain == painter,
    england == red,
    snails == sculptor,
    green + 1 == red,
    blue + 1 == norway,
    doctor == milk,
    japan == diplomat,
    norway == zebra,
    abs(green - white) == 1,
    horse in {diplomat - 1, diplomat + 1},
    italy in {red, white, green}
)
```

In this model, there are many equations. Note also the possibility of using the operator `in`.

3.2 Constraint extension

An `extension` constraint is often referred to as a `table` constraint. It is defined by enumerating (in a set) the tuples of values that are allowed (tuples are called supports) or forbidden (tuples are called conflicts) for a sequence of variables.

A (positive) table constraint is then defined by a scope (a sequence or tuple of variables) `<scope>` and a table (set of tuples of values) `<table>` as follows:

$\langle \text{scope} \rangle \in \langle \text{table} \rangle$

When the table constraint is negative (i.e., enumerates forbidden tuples), we have:

$\langle \text{scope} \rangle \notin \langle \text{table} \rangle$

With X denoting a scope (sequence or tuple of variables), and S and C denoting sets of supports and conflicts, we have the following semantics for non-unary *positive* table constraints:

Semantics 2

`extension(X, S)`, with $X = \langle x_0, x_1, \dots, x_{r-1} \rangle$ and S a set of supports, iff
 $\langle x_0, x_1, \dots, x_{r-1} \rangle \in S$

Prerequisite : $\forall \tau \in S, |\tau| = |X| \geq 2$

and this one for non-unary *negative* table constraints:

Semantics 3

`extension(X, C)`, with $X = \langle x_0, x_1, \dots, x_{r-1} \rangle$ and C a set of conflicts, iff
 $\langle x_0, x_1, \dots, x_{r-1} \rangle \notin C$

Prerequisite : $\forall \tau \in C, |\tau| = |X| \geq 2$

In PyCSP³, we can directly write table constraints in mathematical forms, by using tuples, sets and the operators `in` and `not in`. The scope is given by a tuple of variables on the left of the constraining expression and the table is given by a set of tuples of values on the right of the constraining expression. Although not recommended, it is possible to write scopes and tables under the form of lists.

Traffic Lights. From CSPLib: “Consider a four way traffic junction with eight traffic lights. Four of the traffic lights are for the vehicles and can be represented by the variables v_1 to v_4 with domains $\{r, ry, g, y\}$ (for red, red-yellow, green and yellow). The other four traffic lights are for the pedestrians and can be represented by the variables p_1 to p_4 with domains $\{r, g\}$. The constraints on these variables can be modelled by quaternary constraints on (v_i, p_i, v_j, p_j) for $1 \leq i \leq 4, j = (1 + i) \bmod 4$ which allow just the tuples $\{(r, r, g, g), (ry, r, y, r), (g, g, r, r), (y, r, ry, r)\}$.”

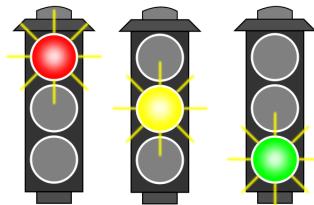

Figure 3.3: How to adjust traffic lights? (image from freesvg.org)

PyCSP³ Model 29

```
from pycsp3 import *

R, RY, G, Y = "red", "red-yellow", "green", "yellow"

# v[i] is the color for the ith vehicle traffic light
v = VarArray(size=4, dom={R, RY, G, Y})

# p[i] is the color for the ith pedestrian traffic light
p = VarArray(size=4, dom={R, G})

table = {(R, R, G, G), (RY, R, Y, R), (G, G, R, R), (Y, R, RY, R)}

satisfy(
    (v[i], p[i], v[(i + 1) % 4], p[(i + 1) % 4]) in table for i in range(4)
)
```

Note how we naturally build a set of tuples (with symbolic values, here). Four quaternary table constraints are posted in this model.

Traveling Tournament with Predefined Venues. From CSPLib: “The TPPV was introduced in [23] and consists of finding an optimal compact single round robin schedule for a sport event. Given a set of n teams, each team has to play against every other team exactly once. In each round, a team plays either at home or away, however no team can play more than two (or three) consecutive times at home or away. The sum of the traveling distance of each team has to be minimized. The particularity of this problem resides on the venue of each game that is predefined, i.e. if team a plays against b it is already known whether the game is going to be held at a ’s home or at b ’s home. The original instances assume symmetric circular distances: for $i \leq j$, $d_{i,j} = d_{j,i} = \min(j - i, i - j + n)$.”

An example of data is given by the following JSON file:

```
{
  "nTeams": 8,
  "predefinedVenues": [
    [0, 1, 1, 0, 0, 0, 0, 1],
    [0, 0, 0, 1, 0, 1, 0, 1],
    ...
  ]
}
```

A PyCSP³ model of this problem is given by the following file:

PyCSP³ Model 30

```
from pycsp3 import *

pv = data.predefinedVenues
nTeams, nRounds = data.nTeams, data.nTeams - 1

def cdist(i, j): # circular distance between i and j
    return min(abs(i - j), nTeams - abs(i - j))

def table_end(i):
    # when playing at home (whatever the opponent, travel distance is 0)
    return {(1, ANY, 0)} | {(0, j, cdist(i, j)) for j in range(nTeams) if j != i}

def table_intern(i):
    return {(1, 1, ANY, ANY, 0)} |
        {(0, 1, j, ANY, circ_distance(j, i)) for j in range(nTeams) if j != i} |
        {(1, 0, ANY, j, circ_distance(i, j)) for j in range(nTeams) if j != i} |
```

```

{(0, 0, j1, j2, circ_distance(j1, j2)) for j1 in range(nTeams)
 for j2 in range(nTeams) if different_values(i, j1, j2)})

def automaton():
    tr = {("q", 0, "q01"), ("q", 1, "q11"), ("q01", 0, "q02"), ("q01", 1, "q11"),
          ("q11", 0, "q01"), ("q11", 1, "q12"), ("q02", 1, "q11"), ("q12", 0, "q01")}
    return Automaton(start="q", final={"q01", "q02", "q11", "q12"}, transitions=tr)

# o[i][k] is the opponent (team) of the ith team at the kth round
o = VarArray(size=[nTeams, nRounds], dom=range(nTeams))

# h[i][k] is 1 iff the ith team plays at home at the kth round
h = VarArray(size=[nTeams, nRounds], dom={0, 1})

# t[i][k] is the travelled distance by the ith team at the kth round.
# An additional round is considered for returning at home.
t = VarArray(size=[nTeams, nRounds + 1], dom=range(nTeams // 2 + 1))

satisfy(
    # a team cannot play against itself
    [o[i][k] != i for i in range(nTeams) for k in range(nRounds)],

    # ensuring predefined venues
    [pv[i][o[i][k]] == h[i][k] for i in range(nTeams) for k in range(nRounds)],

    # ensuring symmetry of games: if team i plays against j, then j plays against i
    [o[:, k][o[i][k]] == i for i in range(nTeams) for k in range(nRounds)],

    # each team plays once against all other teams
    [AllDifferent(row) for row in o],

    # at most 2 consecutive games at home, or consecutive games away
    [h[i] in automaton() for i in range(nTeams)],

    # handling travelling for the first game
    [(h[i][0], o[i][0], t[i][0]) in table_end(i) for i in range(nTeams)],

    # handling travelling for the last game
    [(h[i][-1], o[i][-1], t[i][-1]) in table_end(i) for i in range(nTeams)],

    # handling travelling for two successive games
    [(h[i][k], h[i][k + 1], o[i][k], o[i][k + 1], t[i][k + 1]) in table_intern(i)
     for i in range(nTeams) for k in range(nRounds - 1)]
)

minimize(
    # minimizing summed up travelled distance
    Sum(t)
)

```

Two functions, called `table_end()` and `table_intern()`, are introduced here to build short tables, i.e., tables that contain short tuples (a short tuple is a tuple containing the special symbol `'*'`, denoted in PyCSP³ by the constant `ANY`). When the symbol `'*'` is present, it means that any value from the domain of the corresponding variable can be present at its position. For more information about short tables, see e.g., [21, 31]. Remember that the symbol `|` is used by Python to perform the union of two sets, and that we use the notation `o[:, k]` to extract the `k`th column of the array `o`, as in NumPy. Some `regular` constraints (based on automata) are also posted, but we shall discuss them in the next section.

Subgraph Isomorphism. An instance of the *subgraph isomorphism problem* is defined by a pattern graph $G_p = (V_p, E_p)$ and a target graph $G_t = (V_t, E_t)$: the objective is to determine whether G_p is isomorphic to some subgraph(s) in G_t . Finding a solution to such a problem instance means then finding a *subisomorphism function*, that is an injective mapping $f : V_p \rightarrow V_t$ such that all edges of G_p are preserved: $\forall(v, v') \in E_p, (f(v_p), f(v'_p)) \in E_t$. Here, we refer to the partial, and not the induced subgraph isomorphism problem. An example of data is given by the following JSON file:

```
{
    "nPatternNodes": 180,
    "nTargetNodes": 200,
    "patternEdges": [[0,1], [0,3], [0,17], ...],
    "targetEdges": [[0,34], [0,65], [0,129], ...]
}
```

A PyCSP³ model of this problem is given by the following file:

 **PyCSP³ Model 31**

```
from pycsp3 import *

n, m = data.nPatternNodes, data.nTargetNodes

def structures():
    pe, te = data.patternEdges, data.targetEdges
    p_degrees = [len([e for e in pe if i in e]) for i in range(n)]
    t_degrees = [len([e for e in te if i in e]) for i in range(m)]
    tab = {(i, j) for (i, j) in te} | {(j, i) for (i, j) in te}
    cfs = [[j for j in range(m) if t_degrees[j] < p_degrees[i]] for i in range(n)]
    pl, tl = [i for (i, j) in pe if i == j], [i for (i, j) in te if i == j]
    return pl, tl, tab, cfs

p_loops, t_loops, table, degree_conflicts = structures()

# x[i] is the target node to which the ith pattern node is mapped
x = VarArray(size=n, dom=range(m))

satisfy(
    # ensuring injectivity
    AllDifferent(x),

    # preserving edges
    [(x[i], x[j]) in table for (i, j) in data.patternEdges],

    # being careful of self-loops
    [x[i] in t_loops for i in p_loops],

    # tag(redundant-constraints)
    [x[i] not in tab for i, tab in enumerate(degree_conflicts) if len(tab) > 0]
)
```

In this model, some binary `extension` constraints are posted for preserving edges, and some unary `extension` constraints are posted for handling self-loops as well as for reducing domains by reasoning from node degrees. Note that for a unary `extension` constraint, we use the form: $x \text{ in } S$ where x is a variable of the model and S a set of values.

3.3 Constraint regular

Definition 1 (DFA) A deterministic finite automaton (DFA) is defined by a 5-tuple $(Q, \Sigma, \delta, q_0, F)$ where Q is a finite set of states, Σ is a finite set of symbols called the alphabet, $\delta : Q \times \Sigma \rightarrow Q$ is a transition function, $q_0 \in Q$ is the initial state, and $F \subseteq Q$ is the set of final states.

Given an input string (a finite sequence of symbols taken from the alphabet Σ), the automaton starts in the initial state q_0 , and for each symbol in sequence of the string, applies the transition function to update the current state. If the last state reached is a final state then the input string is accepted by the automaton. The set of strings that the automaton A accepts constitutes a language, denoted by $L(A)$, which is technically a regular language. When the automaton is non-deterministic, we can find two transitions (q_i, a, q_j) and (q_i, a, q_k) such that $q_j \neq q_k$.

A **regular** constraint [9, 25] ensures that the sequence of values assigned to the variables of its scope must belong to a given regular language (i.e., forms a word that can be recognized by a deterministic, or non-deterministic, finite automaton). For such constraints, a DFA is then used to determine whether or not a given tuple is accepted. This can be an attractive approach when constraint relations can be naturally represented by regular expressions in a known regular language. For example, in rostering problems, regular expressions can represent valid patterns of activities. The semantics is:

Semantics 4

```
regular(X, A), with X = ⟨x0, x1, ..., xr-1⟩ and A a finite automaton, iff
x0x1...xr-1 ∈ L(A)
```

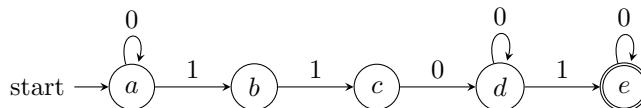

In PyCSP³, we can directly write **regular** constraints in mathematical forms, by using tuples, automatas and the operator **in**. The scope of a constraint is given by a tuple of variables on the left of the constraining expression and an automaton is given on the right of the constraining expression. Automatas in PyCSP³ are objects of Class **Automaton** that are built by calling the following constructor:

```
def __init__(self, *, start, transitions, final):
```

Three named parameters are required:

- **start** is the name of the initial state (a string)
- **transitions** is a set (or list) of 3-tuples
- **final** is the set (or list) of the names of final states (strings)

Note that the set of states and the alphabet can be inferred from **transitions**.

As an example, the constraint defined on scope $\langle x_1, x_2, \dots, x_7 \rangle$ from the simple automation depicted above is given in PyCSP³ by:

```
t = {("a", 0, "a"), ("a", 1, "b"), ("b", 1, "c"), ("c", 0, "d"),
     ("d", 0, "d"), ("d", 1, "e"), ("e", 0, "e")}
automaton = Automaton(start="a", transitions=t, final="e")

staisfy(
    (x1, x2, x3, x4, x5, x6, x7) in automaton,
)
    ...
```

This gives, after compiling to XCSP³:

```
<regular>
<list> x1 x2 x3 x4 x5 x6 x7 </list>
<transitions>
```

```

(a,0,a)(a,1,b)(b,1,c)(c,0,d)(d,0,d)(d,1,e)(e,0,e)
</transitions>
<start> a </start>
<final> e </final>
</regular>

```

Traveling Tournament with Predefined Venues. This problem was introduced in Section 3.2. Here is a snippet of the PyCSP³ model:

```

def automaton():
    tr = {("q", 0, "q01"), ("q", 1, "q11"), ("q01", 0, "q02"), ("q01", 1, "q11"),
          ("q11", 0, "q01"), ("q11", 1, "q12"), ("q02", 1, "q11"), ("q12", 0, "q01")}
    return Automaton(start="q", final={"q01", "q02", "q11", "q12"}, transitions=tr)

satisfy(
    # at most 2 consecutive games at home, or consecutive games away
    [h[i] in automaton() for i in range(nTeams)],
    ...
)

```

3.4 Constraint `mdd`

The constraint `mdd` [11, 12, 13, 24] ensures that the sequence of values assigned to the variables it involves follows a path going from the root of the described MDD (Multi-valued Decision Diagram) to the unique terminal node. Because the graph is directed, acyclic, with only one root node and only one terminal node, we just need to introduce the set of transitions.

Below, $L(M)$ denotes the language recognized by a MDD M .

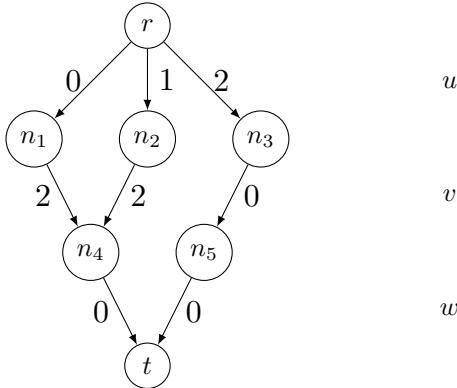

Semantics 5

`mdd(X, M)`, with $X = \langle x_0, x_1, \dots, x_{r-1} \rangle$ and M a MDD, iff
 $x_0 x_1 \dots x_{r-1} \in L(M)$

In PyCSP³, we can directly write `mdd` constraints in mathematical forms, by using tuples, MDDs and the operator `in`. The scope of a constraint is given by a tuple of variables on the left of the constraining expression and an MDD is given on the right of the constraining expression. MDDs in PyCSP³ are objects of Class `MDD` that are built by calling the following constructor:

```
def __init__(self, transitions):
```

The named parameter `transitions` is required: this is a list (not a set) of 3-tuples. As said above, the root and terminal nodes (and the full set of states) can be inferred from `transitions`, if the MDD is well constructed.

As an example, the constraint of scope $\langle u, v, w \rangle$ is defined from the simple MDD depicted above (with root node r and terminal node t) as:

```
t = [("r", 0, "n1"), ("r", 1, "n2"), ("r", 2, "n3"), ("n1", 2, "n4"),
     ("n2", 2, "n4"), ("n3", 0, "n5"), ("n4", 0, "t"), ("n5", 0, "t")]

satisfy(
    (u, v, w) in MDD(t),
    ...
)
```

3.5 Constraint allDifferent (and allDifferentList)

The constraint `allDifferent`, see [27, 30, 16], ensures that the variables in a specified list X must all take different values. A variant, called `allDifferentExcept` in the literature [3, 14], enforces variables to take distinct values, except those that are assigned to some specified values (often, the single value 0). This is the role of the set E below.

Semantics 6

```
allDifferent( $X, E$ ), with  $X = \langle x_0, x_1, \dots \rangle$ , iff
 $\forall (i, j) : 0 \leq i < j < |X|, x_i \neq x_j \vee x_i \in E \vee x_j \in E$ 
allDifferent( $X$ ) iff allDifferent( $X, \emptyset$ )
```

In PyCSP³, to post a constraint `allDifferent`, we must call the function `AllDifferent()` whose signature is:

```
def AllDifferent(term, *others, excepting=None, matrix=None):
```

The two parameters `term` and `others` are positional, and allow us to pass the terms either in sequence (individually) or under the form of a list. The optional named parameter `excepting` indicates the value (or the set of values) that must be ignored, and the optional named parameter `matrix` indicates if a constraint `allDifferent` must be imposed on both rows and columns of a two-dimensional list (`matrix`). More accurately, the terms can be given as:

- o a list of variables, as in `AllDifferent(x)`
- o a sequence of individual variables, as in `AllDifferent(u, v, w)`
- o a generator of variables, as in `AllDifferent(x[i] for i in range(n) if i%2 > 0)`
- o a sequence of individual expressions, as in `AllDifferent(x[1] + 1, x[2] + 2, x[3] + 3)`

- o a generator of expressions, as in `AllDifferent(x[i] + i for i in range(n))`

Now, assuming that x is a two-dimensional list of variables, the matrix variant of `allDifferent` is imposed on x by: `AllDifferent(x, matrix=True)`. If $x = [[p, q, r], [u, v, w]]$, then the posted constraint is equivalent to having posted:

- o `AllDifferent(p,q,r)`
- o `AllDifferent(u,v,w)`
- o `AllDifferent(p,u)`
- o `AllDifferent(q,v)`
- o `AllDifferent(r,w)`

3.6 Constraint `allEqual`

The constraint `allEqual` ensures that all involved variables take the same value.

Semantics 7

`allEqual(X)`, with $X = \langle x_0, x_1, \dots \rangle$, iff
 $\forall (i, j) : 0 \leq i < j < |X|, x_i = x_j$

In Python, we can call the function `AllEqual()` with a list of variables as parameter.

Domino. As an illustration, let us consider the problem Domino that was introduced in [32] to emphasize the sub-optimality of a generic constraint propagation algorithm (called AC3). Each instance, characterized by two integers n and d , is binary and corresponds to an undirected constraint graph with a cycle. More precisely, n denotes the number of variables, each with $\{0, \dots, d - 1\}$ as domain, and there exist:

- o $n - 1$ equality constraints: $x_i = x_{i+1}, \forall i \in \{0, \dots, n - 2\}$
- o a trigger constraint: $(x_0 + 1 = x_{n-1}) \vee (x_0 = x_{n-1} = d - 1)$

A PyCSP³ model of this problem is given by the following file 'Domino.py':

PyCSP³ Model 32

```
from pycsp3 import *

n, d = data.nDominos, data.nValues

# x[i] is the value of the ith domino
x = VarArray(size=n, dom=range(d))

satisfy(
    AllEqual(x),
    (x[0] + 1 == x[-1]) | ((x[0] == x[-1]) & (x[0] == d - 1))
)
```

Of course, it is possible to replace the constraint `allEqual` by:

```
[x[i] == x[i + 1] for i in range(n - 1)],
```

The constraint `allEqual` is mainly introduced for its ease of use.

3.7 Constraints increasing and decreasing

The constraint `ordered` ensures that the variables of a specified list of variables X are ordered in sequence, according to a specified relational operator $\odot \in \{<, \leq, \geq, >\}$. An optional list of integers or variables L indicates the minimum distance between any two successive variables of X .

Semantics 8

```
ordered(X, L, ⊖), with X = ⟨x0, x1, ...⟩, L = ⟨l0, l1, ...⟩ and ⊖ ∈ {<, ≤, ≥, >}, iff
    ∀i : 0 ≤ i < |X| - 1, xi + li ⊖ xi+1
ordered(X, ⊖), with X = ⟨x0, x1, ...⟩ and ⊖ ∈ {<, ≤, ≥, >}, iff
    ∀i : 0 ≤ i < |X| - 1, xi ⊖ xi+1
```

Prerequisite : $|X| = |L| + 1$

In PyCSP³, to post a constraint `ordered`, we must call either the function `Increasing()` or the function `Decreasing()`, whose signatures are:

```
def Increasing(term, *others, strict=False, lengths=None):
def Decreasing(term, *others, strict=False, lengths=None):
```

The two parameters `term` and `others` are positional, and allow us to pass the variables either in sequence (individually) or under the form of a list. The optional named parameter `strict` indicates if the relation must be strict or not, and the optional named parameter `lengths` is for specifying minimum distances. In other words, assuming that $x = [u, v, w]$ is a simple list of variables, ordering variables of x can be imposed by:

- `Increasing(x, strict=True)`
ensuring $u < v < w$
- `Increasing(x)`
ensuring $u \leq v \leq w$
- `Decreasing(x)`
ensuring $u \geq v \geq w$
- `Decreasing(x, strict=True)`
ensuring $u > v > w$

The constraints `increasing` and `decreasing` are mainly an ease of use, as it is possible to post equivalent `intension` constraints. For example, `Increasing(x,strict=True)` can be equivalently written as:

```
[x[i] < x[i+1] for i in range(len(x)-1)]
```

Steiner Triple Systems. From [CSPLib](#): “The ternary Steiner problem of order n consists of finding a set of $n \times (n!)/6$ triples of distinct integer elements in $\{1, 2, \dots, n\}$ such that any two triples have at most one common element. It is a hypergraph problem coming from combinatorial mathematics where n modulo 6 has to be equal to 1 or 3. One possible solution for $n = 7$ is $\{\{1, 2, 3\}, \{1, 4, 5\}, \{1, 6, 7\}, \{2, 4, 6\}, \{2, 5, 7\}, \{3, 4, 7\}, \{3, 5, 6\}\}$. This is a particular case of the more general Steiner system.”

A PyCSP³ model of this problem is given by the following file ‘Steiner3.py’:

PyCSP³ Model 33

```

from pycsp3 import *

n = data.n
nTriples = (n * (n - 1)) // 6

def condition(i1, i2, i3, j1, j2, j3):
    return different_values(i1, i2, i3) and different_values(j1, j2, j3)
    and len({i for i in {i1, i2, i3} if i in {j1, j2, j3}}) <= 1

table = {(i1, i2, i3, j1, j2, j3)
          for (i1, i2, i3, j1, j2, j3) in product(range(1, n + 1), repeat=6)
          if condition(i1, i2, i3, j1, j2, j3)}

# x[i] is the ith triplet of value
x = VarArray(size=[nTriples, 3], dom=range(1, n + 1))

satisfy(
    # ensuring that triples are formed of distinct increasing integers
    [Increasing(x[i], strict=True) for i in range(nTriples)],

    # ensuring that triples share at most one value
    [(x[i] + x[j]) in table for i in range(nTriples) for j in range(i + 1, nTriples)])
)

```

3.8 Constraints lexIncreasing and lexDecreasing

The constraint `ordered` can be naturally lifted to lists, by considering the lexicographic order. Because this constraint is very popular, it is called `lex`, instead of `ordered` over lists of integer variables. The constraint `lex`, see [8, 15], ensures that the tuple formed by the values assigned to the variables of a first specified list X_1 is related to the tuple formed by the values assigned to the variables of a second specified list X_2 with respect to a specified lexicographic order operator $\odot \in \{<_{lex}, \leq_{lex}, \geq_{lex}, >_{lex}\}$. If more than two lists of variables are specified, the entire sequence of tuples must be ordered; this captures then `lexChain` [7].

Semantics 9

`lex(\mathcal{X} , \odot)`, with $\mathcal{X} = \langle X_0, X_1, \dots \rangle$ and $\odot \in \{<_{lex}, \leq_{lex}, \geq_{lex}, >_{lex}\}$, iff
 $\forall i : 0 \leq i < |\mathcal{X}| - 1, \mathbf{X}_i \odot \mathbf{X}_{i+1}$

Prerequisite : $|\mathcal{X}| \geq 2 \wedge \forall i : 0 \leq i < |\mathcal{X}| - 1, |X_i| = |X_{i+1}| \geq 2$

In PyCSP³, to post a constraint `lex`, we must call either the function `LexIncreasing()` or the function `lexDecreasing()`, whose signatures are:

```

def LexIncreasing(term, *others, strict=False, matrix=False):
def LexDecreasing(term, *others, strict=False, matrix=False):

```

The two parameters `term` and `others` are positional, and allow us to pass the lists either in sequence (individually) or under the form of a two-dimensional list. The optional named parameter `strict` indicates if the relation must be strict or not, and the optional named parameter `matrix` indicates if a lexicographic order must be imposed on both rows and columns of a two-dimensional list (`matrix`). In other words, assuming that x , y and z are simple lists of variables, ordering lexicographically x , y and z can be imposed by:

- LexIncreasing(x1, x2, x3, strict=True)
ensuring $x <_{lex} y <_{lex} z$
- LexIncreasing(x1, x2, x3)
ensuring $x \leq_{lex} y \leq_{lex} z$
- LexDecreasing(x1, x2, x3)
ensuring $x \geq_{lex} y \geq_{lex} z$
- LexDecreasing(x1, x2, x3, strict=True)
ensuring $x >_{lex} y >_{lex} z$

Now, assuming that x is a two-dimensional list of variables, the matrix variant of `lex` with \leq_{lex} (for example) as operator is imposed on x by: `LexIncreasing(x, matrix=True)`. If $x = [[p, q, r], [u, v, w]]$, then the posted constraint is equivalent to having posted:

- $(p, q, r) \leq_{lex} (u, v, w)$
- $(p, u) \leq_{lex} (q, v) \leq_{lex} (r, w)$

Social Golfers. “The coordinator of a local golf club has come to you with the following problem. In their club, there are 32 social golfers, each of whom play golf once a week, and always in groups of 4. They would like you to come up with a schedule of play for these golfers, to last as many weeks as possible, such that no golfer plays in the same group as any other golfer on more than one occasion. The problem can easily be generalized to that of scheduling G groups of K golfers over at most W weeks, such that no golfer plays in the same group as any other golfer twice (i.e. maximum socialisation is achieved). For the original problem, the values of G and K are respectively 8 and 4.” See [CSPLib](#).

A PyCSP³ model of this problem is given by the following file ‘SocialGolfers.py’:

PyCSP³ Model 34

```
from pycsp3 import *

nGroups, size, nWeeks = data.nGroups, data.groupSize, data.nWeeks
nPlayers = nGroups * size

# g[w][p] is the group admitting on week w the player p
g = VarArray(size=[nWeeks, nPlayers], dom=range(nGroups))

satisfy(
    # ensuring that two players don't meet more than one time
    [(g[w1][p1] != g[w1][p2]) | (g[w2][p1] != g[w2][p2])
     for w1 in range(nWeeks) for w2 in range(w1 + 1, nWeeks)
     for p1 in range(nPlayers) for p2 in range(p1 + 1, nPlayers)],

    # respecting the size of the groups
    [Cardinality(g[w], occurrences={i: size for i in range(nGroups)})
     for w in range(nWeeks)],

    # tag(symmetry-breaking)
    LexIncreasing(g, matrix=True)
)
```

We have the guarantee of keeping at least one solution if the instance is satisfiable, when the matrix `lex` constraint is posted.

3.9 Constraint sum

The constraint `sum` is one of the most important constraint. This constraint may involve (integer or variable) coefficients, and is subject to a numerical condition (\odot, k) . For example, a form of `sum`, sometimes called `subset-sum` or `knapsack` [29, 26] involves the operator `in`, and ensures that the computed sum belongs to a specified interval. Below, we introduce the semantics while considering a main list X of variables and a list C of coefficients:

Semantics 10

`sum(X, C, (\odot , k))`, with $X = \langle x_0, x_1, \dots \rangle$, and $C = \langle c_0, c_1, \dots \rangle$, iff
 $(\sum_{i=0}^{|X|-1} c_i \times x_i) \odot k$

Prerequisite : $|X| = |C| \geq 2$

In PyCSP³, to post a constraint `sum`, we must call the function `Sum()` whose signature is:

```
def Sum(term, *others):
```

The two parameters `term` and `others` are positional, and allow us to pass the terms either in sequence (individually) or under the form of a list. More accurately, the terms can be given as:

- o a list of variables, as in `Sum(x)`
- o a sequence of individual variables, as in `Sum(u, v, w)`
- o a generator of variables, as in `Sum(x[i] for i in range(n) if i%2 > 0)`
- o a generator of variables, with coefficients, as in `Sum(x[i] * costs[i] for i in range(n))`
- o a generator of expressions, as in `Sum(x[i] > 0 for i in range(n))`
- o a generator of expressions, with coefficients, as in `Sum((x[i] + y[i]) * costs[i] for i in range(n))`

Note that arguments are flattened, meaning that variables (and expressions) are collected from arguments to form a simple list even if multi-dimensional structures (lists) are involved, and while discarding any occurrence of the value `None`. For example, flattening `[[u, v], [None, w]]` gives `[u, v, w]`.

The object obtained when calling `Sum()` must be restricted by a condition (typically, defined by a relational operator and a limit).

Magic Sequence. This problem was introduced in Section 1.2.3. Here is a snippet of the PyCSP³ model:

```
satisfy(
    ...
    # tag(redundant-constraints)
    [
        Sum(x) == n,
        Sum((i - 1) * x[i] for i in range(n)) == 0
    ]
)
```

The first `sum` constraint involves a simple list x of variables whereas the second one involves terms that are products of variables and coefficients.

Importantly, it is possible to combine several objects `Sum` with operators `+` and `-` (and to compare them, which is equivalent to a subtraction). This is illustrated below.

Crypto Puzzle. In crypto-arithmetic problems, digits (values between 0 and 9) are represented by letters. Different letters stand for different digits, and different occurrences of the same letter denote the same digit. The problem is then represented as an arithmetic operation between words. The task is to find out which letter stands for which digit, so that the result of the given arithmetic operation is true.

For example,

$$\begin{array}{r}
 \text{N O} \\
 + \text{ N O} \\
 = \text{ Y E S}
 \end{array}
 \quad
 \begin{array}{r}
 \text{C R O S S} \\
 + \text{ R O A D S} \\
 = \text{ D A N G E R}
 \end{array}
 \quad
 \begin{array}{r}
 \text{D O N A L D} \\
 + \text{ G E R A L D} \\
 = \text{ R O B E R T}
 \end{array}$$

A PyCSP³ model of this problem is given by the following file 'CryptoPuzzle.py':

```

PyCSP3 Model 35

from pycsp3 import *

word1, word2, word3 = data.word1.lower(), data.word2.lower(), data.word3.lower()
letters = set(alphabet_positions(word1 + word2 + word3))
n = len(word1); assert len(word2) == n and len(word3) in {n, n + 1}

# x[i] is the value assigned to the ith letter (if present) of the alphabet
x = VarArray(size=26, dom=lambda i: range(10) if i in letters else None)

# auxiliary lists of variables associated with the three words
x1, x2, x3 = [[x[i] for i in reversed(alphabet_positions(w))]
               for w in [word1, word2, word3]]

satisfy(
    # all letters must be assigned different values
    AllDifferent(x),

    # the most significant letter of each word cannot be equal to 0
    [x1[-1] != 0, x2[-1] != 0, x3[-1] != 0],

    # ensuring the crypto-arithmetic sum
    Sum((x1[i] + x2[i]) * 10 ** i for i in range(n))
    == Sum(x3[i] * 10 ** i for i in range(len(x3)))
)

```

The PyCSP³ function `alphabet_positions()` returns a tuple composed with the position in the alphabet of all letters of a specified string. For example, `alphabet_positions("about")` returns (0, 1, 14, 20, 19). Note how two objects `Sum` are involved. Of course the crypto-arithmetic sum could also have been written as:

```

Sum((x1[i] + x2[i]) * 10 ** i for i in range(n))
- Sum(x3[i] * 10 ** i for i in range(len(x3))) == 0

```

To well understand the way the constraint `sum` is constructed, note that executing:

```
python3 CryptoPuzzle.py -data=[SEND,MORE,MONEY]
```

yields the following XCSP³ file:

```

<instance format="XCSP3" type="CSP">
  <variables>
    <array id="x" note="x[i] is the value assigned to the ith letter (if present) of
      the alphabet" size="[26]"> 0..9 </array>
  </variables>
  <constraints>
    <allDifferent note="all letters must be assigned different values">

```

```

x[3..4] x[12..14] x[17..18] x[24]
</allDifferent>
<group note="the most significant letter of each word cannot be equal to 0">
  <intension> ne(%0,0) </intension>
  <args> x[18] </args>
  <args> x[12] </args>
  <args> x[12] </args>
</group>
<sum note="ensuring the crypto-arithmetic sum">
  <list> add(x[3],x[4]) add(x[13],x[17]) add(x[4],x[14]) add(x[18],x[12])
    x[24] x[4] x[13..14] x[12] </list>
  <coeffs> 1 10 100 1000 -1 -10 -100 -1000 -10000 </coeffs>
  <condition> (eq,0) </condition>
</sum>
</constraints>
</instance>

```

Finally, it is possible to use dot product to build a weighted sum. It means that it suffices to use the operator $*$ between two lists involving variables, integers or expressions to obtain an object `Sum` as e.g., in `[u, v, w] * [2, 4, 3]` which represents $u * 2 + v * 4 + w * 3$. An illustration is given below.

Template Design. From [CSPLib](#): “This problem arises from a colour printing firm which produces a variety of products from thin board, including cartons for human and animal food and magazine inserts. Food products, for example, are often marketed as a basic brand with several variations (typically flavours). Packaging for such variations usually has the same overall design, in particular the same size and shape, but differs in a small proportion of the text displayed and/or in colour. For instance, two variations of a cat food carton may differ only in that on one is printed Chicken Flavour on a blue background whereas the other has Rabbit Flavour printed on a green background. A typical order is for a variety of quantities of several design variations. Because each variation is identical in dimension, we know in advance exactly how many items can be printed on each mother sheet of board, whose dimensions are largely determined by the dimensions of the printing machinery. Each mother sheet is printed from a template, consisting of a thin aluminium sheet on which the design for several of the variations is etched. Each design of carton is made from an identically sized and shaped piece of board. Several cartons can be printed on each mother sheet (in slots), and several different designs can be printed at once, on the same mother sheet. The problem is to decide, firstly, how many distinct templates to produce, and secondly, which variations, and how many copies of each, to include on each template, in order to minimize the amount of waste produced.” More details, and an example, are given on CSPLib.

An example of data is given by the following JSON file:

```
{
  "nSlots": 9,
  "demands": [250, 255, 260, 500, 500, 800, 1100]
}
```

A PyCSP³ model of this problem is given by the following file 'TemplateDesign.py':

PyCSP³ Model 36

```

from pycsp3 import *
from math import ceil, floor

nSlots = data.nSlots
nTemplates = nVariations = len(data.demands)

def variation_interval(v):
    return range(ceil(data.demands[v] * 0.95), floor(data.demands[v] * 1.1) + 1)

# d[i][j] is the number of occurrences of the jth variation on the ith template

```

```

d = VarArray(size=[nTemplates, nVariations], dom=range(nSlots + 1))

# p[i] is the number of printings of the ith template
p = VarArray(size=nTemplates, dom=range(max(data.demands) + 1))

satisfy(
    # all slots of all templates are used
    [Sum(d[i]) == nSlots for i in range(nTemplates)],

    # respecting printing bounds for each variation
    [p * d[:, j] in variation_interval(j) for j in range(nVariations)]
)

minimize(
    # minimizing the number of used templates
    Sum(p[i] > 0 for i in range(nTemplates))
)

```

The two arguments of `satisfy()` correspond to two lists of `sum` constraints; the second list involves dot products, each one built from the array (list) of variables `p` and the j th column of the two-dimensional array (list) `d`, and imposed to belong to a certain interval.

3.10 Constraint count

The constraint `count1`, imposes that the number of variables from a specified list of variables X that take their values from a specified set V respects a numerical condition (\odot, k) . This constraint captures known constraints (usually) called `atLeast`, `atMost`, `exactly` and `among`. To simplify, we assume for the semantics that V is a set of integer values.

Semantics 11

```

count(X, V, ( $\odot$ , k)), with  $X = \langle x_0, x_1, \dots \rangle$ , iff
 $|\{i : 0 \leq i < |X| \wedge x_i \in V\}| \odot k$ 

```

In PyCSP³, to post a constraint `count`, we must call the function `Count()` whose signature is:

```
def Count(term, *others, value=None, values=None):
```

The two parameters `term` and `others` are positional, and allow us to pass the main list of variables X either in sequence (individually) or under the form of a list. The two named parameters allow us to specify either a single value (unique target for counting) or a set of values. Exactly one of these two parameters must be different from `None`. Assuming that x is a list of variables, here are a few examples:

- `Count(x, values={1, 5, 8}) == k`
stands for ' k variables from x must take their values *among* those in $\{1, 5, 8\}$ '
- `Count(x, value=0) > 1`
stands for '*at least* 2 variables from x must be assigned to the value 0'
- `Count(x, value=1) <= k`
stands for '*at most* k variables from x must be assigned to the value 1'
- `Count(x, value=z) == k`
stands for '*exactly* k variables from x must be assigned to the value z '

¹initially introduced in CHIP [2] and Sicstus [10]

Warehouse Location. This problem was introduced in Section 1.3.2. Here is a snippet of the PyCSP³ model:

```
satisfy(
    # capacities of warehouses must not be exceeded
    [Count(w, value=j) <= capacities[j] for j in range(nWarehouses)],

    ...
)
```

Each count constraint imposes that the number of variables in w that take the value j is at most equal to the capacity of the j th warehouse.

Pizza Voucher Problem. From the Intelligent Systems CMPT 417 course at Simon Fraser University. “The problem arises in the University College Cork student dorms. There is a large order of pizzas for a party, and many of the students have vouchers for acquiring discounts in purchasing pizzas. A voucher is a pair of numbers e.g. (2,4), which means if you pay for 2 pizzas then you can obtain for free up to 4 pizzas as long as they each cost no more than the cheapest of the 2 pizzas you paid for. Similarly a voucher (3,2) means that if you pay for 3 pizzas you can get up to 2 pizzas for free as long as they each cost no more than the cheapest of the 3 pizzas you paid for. The aim is to obtain all the ordered pizzas for the least possible cost. Note that not all vouchers need to be used.”

An example of data is given by the following JSON file:

```
{
    "pizzaPrices": [50, 60, 90, 70, 80, 100, 20, 30, 40, 10],
    "vouchers": [
        {"payPart":1,"freePart":2},
        {"payPart":2,"freePart":3},
        ...
    ]
}
```

A PyCSP³ model of this problem is given by the following file 'PizzaVoucher.py':

PyCSP³ Model 37

```
from pycsp3 import *

prices, vouchers = data.pizzaPrices, data.vouchers
nPizzas, nVouchers = len(prices), len(vouchers)

# v[i] is the voucher used for the ith pizza. 0 means that no voucher is used.
# A negative (resp., positive) value i means that the ith pizza contributes
# to the the pay (resp., free) part of voucher |i|.
v = VarArray(size=nPizzas, dom=range(-nVouchers, nVouchers + 1))

# p[i] is the number of paid pizzas wrt the ith voucher
p = VarArray(size=nVouchers, dom=lambda i: {0, vouchers[i].payPart})

# f[i] is the number of free pizzas wrt the ith voucher
f = VarArray(size=nVouchers, dom=lambda i: range(vouchers[i].freePart + 1))

satisfy(
    # counting paid pizzas
    [Count(v, value=-i - 1) == p[i] for i in range(nVouchers)],

    # counting free pizzas
    [Count(v, value=i + 1) == f[i] for i in range(nVouchers)],

    # a voucher, if used, must contribute to have at least one free pizza.
    [iff(f[i] == 0, p[i] != vouchers[i].payPart) for i in range(nVouchers)],
)
```

```

# a free pizza must be cheaper than any pizza paid wrt the used voucher
[(v[i] >= v[j]) | (v[i] != -v[j]) for i in range(nPizzas)
    for j in range(nPizzas) if i != j and prices[i] < prices[j]]
)

minimize(
    # minimizing summed up costs of pizzas
    Sum((v[i] <= 0) * prices[i] for i in range(nPizzas))
)

```

3.11 Constraint nValues

The constraint `nValues` [4], ensures that the number of distinct values taken by the variables of a specified list X respects a numerical condition (\odot, k) . A variant, called `nValuesExcept` [4] discards some specified values of a set E (often, the single value 0).

Semantics 12

```

nValues(X, E, ( $\odot, k$ )), with  $X = \langle x_0, x_1, \dots \rangle$ , iff
 $|\{x_i : 0 \leq i < |X|\} \setminus E| \odot k$ 
nValues(X, ( $\odot, k$ )) iff nValues(X,  $\emptyset$ , ( $\odot, k$ ))

```

In PyCSP³, to post a constraint `nValues`, we must call the function `NValues()` whose signature is:

```
def NValues(term, *others, excepting=None):
```

The two parameters `term` and `others` are positional, and allow us to pass the variables either in sequence (individually) or under the form of a list. The optional named parameter `excepting` allows us to specify a value (integer) or a list of values. The object obtained when calling `NValues()` must be restricted by a condition (typically, defined by a relational operator and a limit).

Board Coloration. This problem was introduced in Section 1.2.2. The constraint `nValues` was introduced for capturing `notAllEqual`.

3.12 Constraint cardinality

The constraint `cardinality`, also called `globalCardinality` or `gcc` in the literature, see [28, 20], ensures that the number of occurrences of each value in a specified set V , taken by the variables of a specified list X , is equal to a specified value (or variable), or belongs to a specified interval (information given by a set O). A Boolean option `closed`, when set to `true`, means that all variables of X must be assigned a value from V .

For simplicity, for the semantics below, we assume that V only contains values and O only contains variables. Note that cl means that `closed` is `true`.

Semantics 13

```

cardinality(X, V, O), with  $X = \langle x_0, x_1, \dots \rangle$ ,  $V = \langle v_0, v_1, \dots \rangle$ ,  $O = \langle o_0, o_1, \dots \rangle$ ,
iff  $\forall j : 0 \leq j < |V|, |\{i : 0 \leq i < |X| \wedge x_i = v_j\}| = o_j$ 
cardinalitycl(X, V, O) iff cardinality(X, V, O)  $\wedge \forall i : 0 \leq i < |X|, x_i \in V$ 

```

Prerequisite : $|X| \geq 2 \wedge |V| = |O| \geq 1$

The form of the constraint obtained by only considering variables in the sets X , V and O is called **distribute** in MiniZinc. In that case, for the semantics, we must additionally guarantee:

$$\forall (i, j) : 0 \leq i < j < |V|, v_i \neq v_j.$$

In PyCSP³, to post a constraint **cardinality**, we must call the function **Cardinality()** whose signature is:

```
def Cardinality(term, *others, occurrences, closed=False):
```

The two parameters **term** and **others** are positional, and allow us to pass the variables either in sequence (individually) or under the form of a list. The value of the required named parameter **occurrences** must be a dictionary: each entry (k, v) in the dictionary means that the number of occurrences of k is given by v . The optional named parameter **closed**, when set to **true**, means that all variables specified by the two positional parameters must be assigned a value that corresponds to a key in the dictionary.

Labeled Dice. From [Jim Orlins Blog](#): “There are 13 words as follows: buoy, cave, celt, flub, fork, hemp, judy, junk, limn, quip, swag, visa, wish. There are 24 different letters that appear in the 13 words. The question is: can one assign the 24 letters to 4 different cubes so that the four letters of each word appears on different cubes. There is one letter from each word on each cube. The puzzle was created by Humphrey Dudley”

A PyCSP³ model of this problem is given by the following file ‘LabeledDice.py’:

PyCSP³ Model 38

```
from pycsp3 import *

words = ["buoy", "cave", "celt", "flub", "fork", "hemp",
         "judy", "junk", "limn", "quip", "swag", "visa"]

# x[i] is the cube where the ith letter of the alphabet is put
x = VarArray(size=26, dom=lambda i: range(1, 5)
              if any(i in alphabet_positions(w) for w in words) else None)

satisfy(
    # the four letters of each word appears on different cubes
    [AllDifferent(x[i] for i in alphabet_positions(w)) for w in words],

    # each cube is assigned 6 letters
    Cardinality(x, occurrences={i: 6 for i in range(1, 5)})
)
```

The PyCSP³ function **alphabet_positions()** returns a tuple composed with the position in the alphabet of all letters of a specified string. For example, **alphabet_positions("about")** returns $(0, 1, 14, 20, 19)$. The posted **cardinality** constraint ensures that we have 6 letters per cube (using an index i for cubes, ranging from 1 to 4).

Magic Sequence. This problem was introduced in Section 1.2.3. Here is a snippet of the PyCSP³ model:

```
# x[i] is the ith value of the sequence
x = VarArray(size=n, dom=range(n))

satisfy(
```

```

# each value i occurs exactly x[i] times in the sequence
Cardinality(x, occurrences={i: x[i] for i in range(n)}),
...
)

```

Here, one can see that variables are used for counting the number of occurrences, and besides, this is a special case where these variables are from the main list (first parameter x).

Sports Scheduling. From CSPLib: “The problem is to schedule a tournament of n teams over $n - 1$ weeks, with each week divided into $n/2$ periods, and each period divided into two slots. The first team in each slot plays at home, whilst the second plays the first team away. A tournament must satisfy the following three constraints:

- every team plays once a week;
- every team plays at most twice in the same period over the tournament;
- every team plays every other team.

”

A PyCSP³ model of this problem is given by the following file ‘SportsScheduling.py’:

PyCSP³ Model 39

```

from pycsp3 import *

nTeams = data.nTeams
nWeeks, nPeriods = nTeams - 1, nTeams // 2
nMatches = (nTeams - 1) * nTeams // 2

def match_number(t1, t2):
    return nMatches - ((nTeams - t1) * (nTeams - t1 - 1)) // 2 + (t2 - t1 - 1)

table = {(t1, t2, match_number(t1, t2)) for t1 in range(nTeams)
          for t2 in range(t1 + 1, nTeams)}

# h[w][p] is the home team at week w and period p
h = VarArray(size=[nWeeks, nPeriods], dom=range(nTeams))

# a[w][p] is the away team at week w and period p
a = VarArray(size=[nWeeks, nPeriods], dom=range(nTeams))

# m[w][p] is the number of the match at week w and period p
m = VarArray(size=[nWeeks, nPeriods], dom=range(nMatches))

satisfy(
    # linking variables through ternary table constraints
    [(h[w][p], a[w][p], m[w][p]) in table for w in range(nWeeks)
     for p in range(nPeriods)],

    # all matches are different (no team can play twice against another team)
    AllDifferent(m),

    # each week, all teams are different (each team plays each week)
    [AllDifferent(h[w] + a[w]) for w in range(nWeeks)],

    # each team plays at most two times in each period
    [Cardinality(h[:, p] + a[:, p], occurrences={t: range(1, 3)
                                                 for t in range(nTeams)}) for p in range(nPeriods)],
)

```

Here, we can see that the interval 1..2 (given by `range(1,3)`) is used to control the number of occurrences of each team in each period, when posting cardinality constraints. Note that we could add some symmetry breaking constraints to the model.

3.13 Constraint maximum

The constraint **maximum** ensures that the maximum value among those assigned to the variables of a specified list X respects a numerical condition (\odot, k) .

A small icon of a yellow book with a grey spine, located in the bottom right corner of the slide.

Semantics 14

maximum($X, (\odot, k)$), with $X = \langle x_0, x_1, \dots \rangle$, iff
 $\max\{x_i : 0 \leq i < |X|\} \odot k$

In PyCSP³, to post a constraint `maximum`, we must call the function `Maximum()` whose signature is:

```
def Maximum(term, *others)
```

The two parameters `term` and `others` are positional, and allow us to pass the variables either in sequence (individually) or under the form of a list. The object obtained when calling `Maximum()` must be restricted by a condition (typically, defined by a relational operator and a limit).

Open Stacks. From Steven Prestwich: “A manufacturer has a number of orders from customers to satisfy. Each order is for a number of different products, and only one product can be made at a time. Once a customer’s order is started a stack is created for that customer. When all the products that a customer requires have been made the order is sent to the customer, so that the stack is closed. Because of limited space in the production area, the number of stacks that are simultaneously open should be minimized.”

An example of data is given by the following JSON file:

Each row of `orders` corresponds to a customer order indicating with 0 or 1 if the j th product is needed. A PyCSP³ model of this problem is given by the following file '`OpenStacks.py`':

PyCSP³ Model 40

```

from pycsp3 import *

orders = data.orders
n = len(orders)      # n orders (customers)
m = len(orders[0])   # m possible products

def table(t):
    return { (ANY, te, 0) for te in range(t) } |
           { (ts, ANY, 0) for ts in range(t + 1, m) } |
           { (ts, te, 1) for ts in range(t + 1) for te in range(t, m) }

# p[j] is the period (time) of the jth product
p = VarArray(size=m, dom=range(m))

```

```

# s[i] is the starting time of the ith stack
s = VarArray(size=n, dom=range(m))

# e[i] is the ending time of the ith stack
e = VarArray(size=n, dom=range(m))

# o[i][t] is 1 iff the ith stack is open at time t
o = VarArray(size=[n, m], dom={0, 1})

# ns[t] is the number of open stacks at time t
ns = VarArray(size=m, dom=range(m + 1))

satisfy(
    # all products are scheduled at different times
    AllDifferent(p),

    # computing starting times of stacks
    [Minimum(p[j] for j in range(m) if orders[i][j] == 1) == s[i] for i in range(n)],

    # computing ending times of stacks
    [Maximum(p[j] for j in range(m) if orders[i][j] == 1) == e[i] for i in range(n)],

    # inferring when stacks are open
    [(s[i], e[i], o[i][t]) in table(t) for i in range(n) for t in range(m)],

    # computing the number of open stacks at any time
    [Sum(o[:, t]) == ns[t] for t in range(m)]
)

minimize(
    # minimizing the number of stacks that are simultaneously open
    Maximum(ns)
)

```

Note that each list of variables is given to `Maximum()` under the form of a comprehension list (generator). The PyCSP³ function `Maximum()` is also used for building the expression to be minimized.

3.14 Constraint minimum

The constraint `minimum` ensures that the minimum value among those assigned to the variables of a specified list X respects a numerical condition (\odot, k) .

Semantics 15

```

minimum(X, ( $\odot, k$ )), with  $X = \langle x_0, x_1, \dots \rangle$ , iff
 $\min\{x_i : 0 \leq i < |X|\} \odot k$ 

```

In PyCSP³, to post a constraint `minimum`, we must call the function `Minimum()` whose signature is:

```
def Minimum(term, *others)
```

The two parameters `term` and `others` are positional, and allow us to pass the variables either in sequence (individually) or under the form of a list. The object obtained when calling `Minimum()` must be restricted by a condition (typically, defined by a relational operator and a limit).

Open Stacks. See the model introduced in the previous section.

3.15 Constraint element

The constraint `element` [19] ensures that the element of a specified list X at a specified index i has a specified value v . The semantics is $X[i] = v$, or equivalently:

Semantics 16

```
element(X, i, v), with X = ⟨x0, x1, ...⟩, iff  
xi = v
```

It is important to note that i must be an integer variable (and not a constant). In Python, to post an `element` constraint, we use the facilities offered by the language, meaning that we can write expressions involving relational and indexing (`[]`) operators.

There are three variants of `element`:

- o variant 1: X is a list of variables, i is an integer variable and v is an integer variable
- o variant 2: X is a list of variables, i is an integer variable and v is an integer (constant)
- o variant 3: X is a list of integers, i is an integer variable and v is an integer variable

Although the variant 3 can be reformulated as a binary extensional constraint, it is often used when modeling.

The Sandwich case. From beCool (UCLouvain): “Someone in the university ate Alice’s sandwich at the cafeteria. We want to find out who the culprit is. The witnesses are unanimous about the following facts:

1. Three persons were in the cafeteria at the time of the crime: Alice, Bob, and Sascha.
2. The culprit likes Alice.
3. The culprit is taller than Alice.
4. Nobody is taller than himself.
5. If A is taller than B, then B is not taller than A.
6. Bob likes no one that Alice likes.
7. Alice likes everybody except Bob.
8. Sascha likes everyone that Alice likes.
9. Nobody likes everyone.

”

This is a single problem (no external data is required). A PyCSP³ model of this problem is given by the following file ‘Sandwich.py’:

PyCSP³ Model 41

```
from pycsp3 import *

alice, bob, sascha = 0, 1, 2

# culprit is among alice (0), bob (1) and sascha (2)
culprit = Var(dom=range(3))

# likes[i][j] is 1 iff the ith guy likes the jth guy
likes = VarArray(size=[3, 3], dom={0, 1})
```

```

# taller[i][j] is 1 iff the ith guy is taller than the jth guy
taller = VarArray(size=[3, 3], dom={0, 1})

satisfy(
    # the culprit likes Alice
    likes[culprit][alice] == 1,

    # the culprit is taller than Alice
    taller[culprit][alice] == 1,

    # nobody is taller than himself
    [taller[i][i] == 0 for i in range(3)],

    # the ith guy is taller than the jth guy iff the reverse is not true
    [taller[i][j] != taller[j][i] for i in range(3) for j in range(3) if i != j],

    # Bob likes no one that Alice likes
    [imply(likes[alice][i], ~likes[bob][i]) for i in range(3)],

    # Alice likes everybody except Bob
    [likes[alice][i] == 1 for i in range(3) if i != bob],

    # Sascha likes everyone that Alice likes
    [imply(likes[alice][i], likes[sascha][i]) for i in range(3)],

    # nobody likes everyone
    [Count(likes[i], value=0) >= 1 for i in range(3)]
)

```

The variant 2 of `element` is illustrated by:

```
likes[culprit][alice] == 1,
```

as it basically encodes “the variable at index `culprit` in the column 0 (`alice`) of the 2-dimensional array of variables `likes` must be equal to 1”.

Warehouse Location. This problem was introduced in Section 1.3.2. Here is a snippet of the PyCSP³ model:

```

satisfy(
    ...

    # computing the cost of supplying the ith store
    [costs[i][w[i]] == c[i] for i in range(nStores)]
)

```

The variant 3 of `element` is illustrated by:

```
costs[i][w[i]] == c[i]
```

as it basically encodes “the variable at index `w[i]` in the `i`th row of the 2-dimensional array of integers `costs` must be equal to `c[i]`”.

It is also possible to use a variant of `element` on matrices, i.e., by using two indexes given by integer variables.

3.16 Constraint channel

The first variant of the constraint `channel` is defined on a single list of variables, and ensures that if the *i*th variable of the list is assigned the value *j*, then the *j*th variable of the same list must be assigned the value *i*.

Semantics 17

`channel(X)`, with $X = \langle x_0, x_1, \dots \rangle$, iff
 $\forall i : 0 \leq i < |X|, x_i = j \Rightarrow x_j = i$

A second classical variant of `channel`, sometimes called `inverse` or `assignment` in the literature, is defined from two separate lists (of the same size) of variables. It ensures that the value assigned to the i th variable of the first list gives the position of the variable of the second list that is assigned to i , and vice versa.

Semantics 18

`channel(X, Y)`, with $X = \langle x_0, x_1, \dots \rangle$ and $Y = \langle y_0, y_1, \dots \rangle$, iff
 $\forall i : 0 \leq i < |X|, x_i = j \Leftrightarrow y_j = i$

Prerequisite: $2 \leq |X| = |Y|$

It is also possible to use this form of `channel`, with two lists of different sizes. The constraint then imposes restrictions on all variables of the first list, but not on all variables of the second list. The syntax is the same, but the semantics is the following (note that the equivalence has been replaced by an implication):

Semantics 19

`channel(X, Y)`, with $X = \langle x_0, x_1, \dots \rangle$ and $Y = \langle y_0, y_1, \dots \rangle$, iff
 $\forall i : 0 \leq i < |X|, x_i = j \Rightarrow y_j = i$

Prerequisite: $2 \leq |X| < |Y|$

Finally, a third variant of `channel` is obtained by considering a list of 0/1 variables to be channeled with an integer variable. This third form of constraint `channel` ensures that the only variable of the list that is assigned to 1 is at an index (position) that corresponds to the value assigned to the stand-alone integer variable.

Semantics 20

`channel(X, v)`, with $X = \{x_0, x_1, \dots\}$, iff
 $\forall i : 0 \leq i < |X|, x_i = 1 \Leftrightarrow v = i$
 $\exists i : 0 \leq i < |X| \wedge x_i = 1$

In PyCSP³, to post a constraint `channel`, we must call the function `Channel()` whose signature is:

```
def Channel(list1, list2=None, *, start_index1=0, start_index2=0):
```

For the first variant, in addition to the positional parameter `list1`, one may use the optional attribute `start_index1` that gives the number used for indexing the first variable in this list (0, by default). For the second variant, two lists must be specified, and optionally the two named parameters can be used. For the third variant, the positional parameter `list2` must be a variable (or a list only containing one variable).

Blackhole. This problem was introduced in Section 1.3.3. Here is a snippet of the PyCSP³ model:

```

...
# x[i] is the value j of the card at position i of the stack
x = VarArray(size=nCards, dom=range(nCards))

# y[j] is the position i of the card whose value is j
y = VarArray(size=nCards, dom=range(nCards))

satisfy(
    Channel(x, y),
    ...
)

```

The constraint `channel` (second variant) links the dual roles of variables from arrays x and y .

Progressive Party Problem. From CSPLib: “The problem is to timetable a party at a yacht club. Certain boats are to be designated hosts, and the crews of the remaining boats in turn visit the host boats for several successive half-hour periods. The crew of a host boat remains on board to act as hosts while the crew of a guest boat together visits several hosts. Every boat can only hold a limited number of people at a time (its capacity) and crew sizes are different. The total number of people aboard a boat, including the host crew and guest crews, must not exceed the capacity. A guest boat cannot revisit a host and guest crews cannot meet more than once. The problem facing the rally organizer is that of minimizing the number of host boats.”

An example of data is given by the following JSON file:

```
{
  "nPeriods": 5,
  "boats": [
    {"crewSize": 2, "capacity": 6},
    {"crewSize": 2, "capacity": 8},
    ...
  ]
}
```

A PyCSP³ model of this problem is given by the following file 'ProgressiveParty.py':

PyCSP³ Model 42

```

from pycsp3 import *

nPeriods = data.nPeriods
boats, nBoats = data.boats, len(data.boats)
crews = [boat.crewSize for boat in boats]

# h[b] indicates if the boat b is a host boat
h = VarArray(size=nBoats, dom={0, 1})

# s[b][p] is the scheduled (visited) boat by the crew of boat b at period p
s = VarArray(size=[nBoats, nPeriods], dom=range(nBoats))

# g[b1][p][b2] is 1 if s[b1][p] = b2
g = VarArray(size=[nBoats, nPeriods, nBoats], dom={0, 1})

satisfy(
    # identifying host boats (when receiving)
    [iff(s[b][p] == b, h[b]) for b in range(nBoats) for p in range(nPeriods)],

    # identifying host boats (when visiting)
    [imply(s[b1][p] == b2, h[b2]) for b1 in range(nBoats) for b2 in range(nBoats)
     if b1 != b2 for p in range(nPeriods)],

```

```

# channeling variables from arrays s and g
[Channel(g[b][p], s[b][p]) for b in range(nBoats) for p in range(nPeriods)],

# boat capacities must be respected
[g[:, p, b] * crews <= boats[b].capacity for b in range(nBoats)
 for p in range(nPeriods)],

# a guest crew cannot revisit a host
[AllDifferent(s[b]), excepting=b) for b in range(nBoats)],

# guest crews cannot meet more than once
[Sum(s[b1][p] == s[b2][p] for p in range(nPeriods)) <= 2
 for b1 in range(nBoats) for b2 in range(b1 + 1, nBoats)]
]

minimize(
    # minimizing the number of host boats
    Sum(h)
)

```

This is the third variant of `channel` that is used here: `g[b][p]` is an array of 0/1 variables while `s[b][p]` is a stand-alone integer variable. Below, note how the symbol ':' is used to take a complete slice of a 3-dimensional array of variables, when posting constraints about boat capacities. Instead, we could have written:

```

[[g[i][p][b] for i in range(nBoats)] * crews <= boats[b].capacity
 for b in range(nBoats) for p in range(nPeriods)],

```

Concerning the last list of `sum` constraints, as the Boolean expression `s[b1][p] == s[b2][p]` is considered to return integers, 0 for false and 1 for true, it is possible to perform a summation.

3.17 Constraint noOverlap

We start with the one dimensional form of `noOverlap` [20] that corresponds to `disjunctive` [6] and ensures that some objects (e.g., tasks), defined by their origins (e.g., starting times) and lengths (e.g., durations), must not overlap. The semantics is given by:

Semantics 21

`noOverlap(X, L)`, with $X = \langle x_0, x_1, \dots \rangle$ and $L = \langle l_0, l_1, \dots \rangle$, iff
 $\forall (i, j) : 0 \leq i < j < |X|, x_i + l_i \leq x_j \vee x_j + l_j \leq x_i$

Prerequisite : $|X| = |L| \geq 2$

In PyCSP³, to post a constraint `noOverlap`, we must call the function `NoOverlap()` whose signature is:

```

def NoOverlap(*, origins, lengths, zero_ignored=False):

```

Note that all parameters must be named (see '*' at first position), and that the parameter `zero_ignored` is optional (value `False` by default). If ever we are in a situation where there exist some zero-length object(s), then if the parameter `zero_ignored` is set to `False`, it indicates that zero-length objects cannot be packed anywhere (cannot overlap with other objects). Arguments given to `origins` and `lengths` when calling the function `NoOverlap()` are expected to be lists of the same length; `origins` must be given a list of variables whereas `lengths` must be given either a list of variables or a list of integers.

Flow Shop Scheduling. From Wikipedia: “There are n machines and m jobs. Each job contains exactly n operations. The i th operation of the job must be executed on the i th machine. No machine can perform more than one operation simultaneously. For each operation of each job, execution time is specified. Operations within one job must be performed in the specified order. The first operation gets executed on the first machine, then (as the first operation is finished) the second operation on the second machine, and so on until the n th operation. Jobs can be executed in any order, however. Problem definition implies that this job order is exactly the same for each machine. The problem is to determine the optimal such arrangement, i.e. the one with the shortest possible total job execution makespan.”

To specify a problem instance, we just need a two-dimensional array of integers for recording durations, as in the following JSON file:

```
{
  "durations": [
    [26, 59, 78, 88, 69],
    [38, 62, 90, 54, 30],
    ...
  ]
}
```

A PyCSP³ model of this problem is given by the following file 'FlowShopScheduling.py':

PyCSP³ Model 43

```
from pycsp3 import *

durations = data.durations # durations[i][j] is the duration of op. j for job i
n, m = len(durations), len(durations[0])
horizon = sum(sum(t) for t in durations) + 1

# s[i][j] is the start time of the jth operation for the ith job
s = VarArray(size=[n, m], dom=range(horizon))

# e[i] is the end time of the last operation for the ith job
e = VarArray(size=n, dom=range(horizon))

satisfy(
    # operations must be ordered on each job
    Increasing(s[i], lengths=durations[i]) for i in range(n),

    # computing the end time of each job
    [e[i] == s[i][-1] + durations[i][-1] for i in range(n)],

    # no overlap on resources
    [NoOverlap(origins=s[:, j], lengths=durations[:, j]) for j in range(m)])
)

minimize(
    # minimizing the makespan
    Maximum(e)
)
```

In this model, for each operation (or equivalently, machine) j , we collect the list of variables from the j th column of s and the list of integers from the j th column of $durations$ when posting a constraint `noOverlap`. Remember that the notation $[:, j]$ stands for the j th column of a two-dimensional array (list).

The k -dimensional form of `noOverlap` corresponds to `diffn` [2] and ensures that, given a set of n -dimensional boxes; for any pair of such boxes, there exists at least one dimension where one box is after the other, i.e., the boxes do not overlap. The semantics is:

Semantics 22

`noOverlap(\mathcal{X}, \mathcal{L})`, with $\mathcal{X} = \langle (x_{1,1}, \dots, x_{1,n}), (x_{2,1}, \dots, x_{2,n}), \dots \rangle$ and
 $\mathcal{L} = \langle (l_{1,1}, \dots, l_{1,n}), (l_{2,1}, \dots, l_{2,n}), \dots \rangle$, iff
 $\forall (i, j) : 1 \leq i < j \leq |\mathcal{X}|, \exists k \in 1..n : x_{i,k} + l_{i,k} \leq x_{j,k} \vee x_{j,k} + l_{j,k} \leq x_{i,k}$

Prerequisite : $|\mathcal{X}| = |\mathcal{L}| \geq 2$

In PyCSP³, to post a constraint `noOverlap`, we must call the function `NoOverlap()` whose signature is:

```
def NoOverlap(*, origins, lengths, zero_ignored=False):
```

Note that all parameters must be named (see '*' at first position), and that the parameter `zero_ignored` is optional (value `False` by default). If ever we are in a situation where there exist some zero-length box(es), then if the parameter `zero_ignored` is set to `False`, it indicates that zero-length boxes cannot be packed anywhere (cannot overlap with other boxes). Arguments given to `origins` and `lengths` when calling the function `NoOverlap()` are expected to be two-dimensional lists of the same length; `origins` must only involve variables whereas `lengths` must involve either only variables or only integers.

Rectangle packing problem. The rectangle packing problem consists of finding a way of putting a given set of rectangles (boxes) in an enclosing rectangle (container) without overlap.

An example of data is given by the following JSON file:

```
{
  "container": {"width": 112, "height": 112},
  "boxes": [
    {"width": 2, "height": 2},
    {"width": 4, "height": 4},
    ...
  ]
}
```

A PyCSP³ model of this problem is given by the following file 'RectanglePacking.py':

PyCSP³ Model 44

```
from pycsp3 import *

width, height = data.container.width, data.container.height
boxes = data.boxes
nBoxes = len(boxes)

# x[i] is the x-coordinate where is put the ith box (rectangle)
x = VarArray(size=nBoxes, dom=range(width))

# y[i] is the y-coordinate where is put the ith box (rectangle)
y = VarArray(size=nBoxes, dom=range(height))

satisfy(
    # unary constraints on x
    [x[i] + boxes[i].width <= width for i in range(nBoxes)],

    # unary constraints on y
    [y[i] + boxes[i].height <= height for i in range(nBoxes)],

    # no overlap on boxes
    NoOverlap(origins=[(x[i], y[i]) for i in range(nBoxes)],
```

```

        lengths=[(box.width, box.height) for box in boxes]),

# tag(symmetry-breaking)
[
    x[-1] <= math.floor((width - boxes[-1].width) // 2.0),
    y[-1] <= x[-1]
] if width == height else None
)

```

3.18 Constraint Cumulative

The constraint `cumulative` is useful when a resource of limited quantity must be shared for achieving several tasks. So, the context is to manage a collection of tasks, each one being described by 4 attributes: its starting time `origin`, its length or duration `length`, its stopping time `end` and its resource consumption `height`. Usually, the values for `length` and `height` are given while the values for `origin` (and `end` by deduction) must be computed.

The constraint `cumulative` [1] enforces that at each point in time, the cumulated height of tasks that overlap that point, respects a numerical condition (\odot, k) . The semantics is given by:

Semantics 23

`cumulative($X, L, H, (\odot, k)$)`, with $X = \langle x_0, x_1, \dots \rangle$, $L = \langle l_0, l_1, \dots \rangle$, $H = \langle h_0, h_1, \dots \rangle$, iff
 $\forall t \in \mathbb{N}, \sum \{h_i : 0 \leq i < |H| \wedge x_i \leq t < x_i + l_i\} \odot k$

Prerequisite : $|X| = |L| = |H| \geq 2$

If the attributes `end` are present while reasoning, we have additionally a set $E = \langle e_0, e_1, \dots \rangle$ such that:

$$\forall i : 0 \leq i < |X|, x_i + l_i = e_i$$

In PyCSP³, to post a constraint `cumulative`, we must call the function `Cumulative()` whose signature is:

```
def Cumulative(*, origins, lengths, heights, ends=None):
```

Note that all parameters must be named (see '*' at first position) and the parameter `ends` is optional (value `None` by default). Arguments given when calling the function are expected to be lists of the same length. The object obtained when calling `Cumulative()` must be restricted by a condition (typically, defined by a relational operator and a limit).

Rcpsp. From CSPLib: “The resource-constrained project scheduling problem is a classical problem in operations research. A number of activities are to be scheduled. Each activity has a duration and cannot be interrupted. There are a set of precedence relations between pairs of activities which state that the second activity must start after the first has finished. There are a set of renewable resources. Each resource has a maximum capacity and at any given time slot no more than this amount can be in use. Each activity has a demand (possibly zero) on each resource. The problem is usually stated as an optimisation problem where the makespan (i.e., the completion time of the last activity) is minimised.” See [CSPLib–Problem 061](#) for more information.

An example of data is given by the following JSON file:

```
{
    "horizon": 158,
```

```

    "resourceCapacities": [12,13,4,12],
    "jobs": [
        {"duration":0, "successors": [1,2,3], "requiredQuantities": [0,0,0,0]}, 
        {"duration":8, "successors": [5,10,14], "requiredQuantities": [4,0,0,0]}, 
        ...
    ]
}

```

A PyCSP³ model of this problem is given by the following file 'Rcpsp.py':

PyCSP³ Model 45

```

from pycsp3 import *

horizon = data.horizon
capacities = data.resourceCapacities
jobs, nJobs = data.jobs, len(data.jobs)

def cumulative_for(k):
    indexes = [i for i in range(nJobs) if jobs[i].requiredQuantities[k] > 0]
    origins = [s[i] for i in indexes]
    lengths = [jobs[i].duration for i in indexes]
    heights = [jobs[i].requiredQuantities[k] for i in indexes]
    return Cumulative(origins=origins, lengths=lengths, heights=heights)

# s[i] is the starting time of the ith job
s = VarArray(size=nJobs, dom=lambda i: {0} if i == 0 else range(horizon))

satisfy(
    # precedence constraints
    [s[i] + job.duration <= s[j] for i, job in enumerate(jobs)
     for j in job.successors],

    # resource constraints
    [cumulative_for(k) <= capacity for k, capacity in enumerate(capacities)])
)

minimize(
    s[-1]
)

```

Observe how the `Cumulative` object returned by the local function call `cumulative_for(k)` is imposed to be less than or equal to the capacity of the k th resource.

3.19 Constraint Circuit

Sometimes, problems involve graphs that are defined with integer variables (encoding called “successors variables”). In that context, graph-based constraints, like `circuit`, involve a main list of variables x_0, x_1, \dots . The assumption is that each pair (i, x_i) represents an arc (or edge) of the graph to be built; if $x_i = j$, then it means that the successor of node i is node j . Note that a *loop* (also called self-loop) corresponds to a variable x_i such that $x_i = i$.

The constraint `circuit` [2] ensures that the values taken by the variables of the specified list forms a circuit, with the assumption that each pair (i, x_i) represents an arc. It is also possible to indicates that the circuit must be of a given size (strictly greater than 1). The semantics is given by:

Semantics 24

```
circuit( $X$ ), with  $X = \langle x_0, x_1, \dots \rangle$ , iff // capture subcircuit
   $\{(i, x_i) : 0 \leq i < |X| \wedge i \neq x_i\}$  forms a circuit of size  $> 1$ 
circuit( $X, s$ ), with  $X = \langle x_0, x_1, \dots \rangle$ , iff
   $\{(i, x_i) : 0 \leq i < |X| \wedge i \neq x_i\}$  forms a circuit of size  $s > 1$ 
```

In PyCSP³, to post a constraint `circuit`, we must call the function `Circuit()` whose signature is:

```
def Circuit(term, *others, start_index=0, size=None):
```

The two first parameters `term` and `others` are positional, and allow us to pass the “successors variables” either in sequence (individually) or under the form of a list. The two other parameters are optional (and must be named): `start_index` gives the number used for indexing the first variable of the specified list (0, by default), and `size` indicates that the circuit must be of a given size (`None` by default indicates that no specific size is required).

It is important to note that the circuit is not required to cover all nodes (the nodes that are not present in the circuit are then self-looping). Hence `circuit`, with loops being simply ignored, basically represents `subcircuit` (e.g., in MiniZinc). If ever you need a full circuit (i.e., without any loop), you have three solutions:

- o indicate with `size` the number of successor variables
- o initially define the variables without the self-looping values,
- o post unary constraints.

Mario. From Amaury Ollagnier and Jean-Guillaume Fages, in the context of the 2013 Minizinc Competition: “This models a routing problem based on a little example of Mario’s day. Mario is an Italian Plumber and his work is mainly to find gold in the plumbing of all the houses of the neighborhood. Mario is moving in the city using his kart that has a specified amount of fuel. Mario starts his day of work from his house and always ends to his friend Luigi’s house to have the supper. The problem here is to plan the best path for Mario in order to earn the more money with the amount of fuel of his kart. From a more general point of view, the problem is to find a path in a graph:

- o path endpoints are given (from Mario’s to Luigi’s)
- o the sum of weights associated to arcs in the path is restricted (fuel consumption)
- o the sum of weights associated to nodes in the path has to be maximized (gold coins)

”

An example of data is given by the following JSON file:

```
{
  "marioHouse": 0,
  "luigiHouse": 1,
  "fuelLimit": 2000,
  "houses": [
    {
      "fuelConsumption": [0, 221, 274, 80, 13, 677, 670, 921, 93, 969, 13, 18, 217, 86, 322],
      "gold": 0
    },
    {
      "fuelConsumption": [0, 0, 702, 83, 813, 679, 906, 246, 35, 529, 79, 528, 451, 242, 712],
      "gold": 0
    },
    ...
  ]
}
```

A PyCSP³ model² of this problem is given by the following file 'Mario.py':

PyCSP³ Model 46

```

from pycsp3 import *

marioHouse, luigiHouse = data.marioHouse, data.luigiHouse
fuelLimit = data.fuelLimit
houses, nHouses = data.houses, len(data.houses)
fuels = [house.fuelConsumption for house in houses]

# s[i] is the house succeeding to the ith house (itself if not part of the route)
s = VarArray(size=nHouses, dom=range(nHouses))

# f[i] is the fuel consumed at each step (from house i to its successor)
f = VarArray(size=nHouses, dom=lambda i: set(fuels[i]))

satisfy(
    # fuel consumption at each step
    [fuels[i][s[i]] == f[i] for i in range(nHouses)],

    # we cannot consume more than the available fuel
    Sum(f) <= fuelLimit,

    # Mario must make a tour (not necessarily complete)
    Circuit(s),

    # Mario's house succeeds to Luigi's house
    s[luigiHouse] == marioHouse
)

maximize(
    # maximizing collected gold
    Sum((s[i] != i) * houses[i].gold for i in range(nHouses)
        if i not in {marioHouse, luigiHouse})
)

```

For linking variables from arrays s and f , we use some `element` constraints. Note how lists $\text{fuels}[i]$ involved in these constraints can be directly indexed by variables (objects). This is because the type of $\text{fuels}[i]$ is a PyCSP³ subclass of 'list'; and this is automatically handled when loading the JSON file. Suppose that we hould have written instead:

```
fuels = [[v for v in house.fuelConsumption] for house in houses]
```

Here, $\text{fuels}[i]$ would be a simple 'list', and we would get an error when compiling. In that case, to fix the problem, it is possible to call the PyCSP³ function `cp_array()`:

```
fuels = [cp_array(v for v in house.fuelConsumption) for house in houses]
```

but of course, the code we have chosen for our model above is simpler.

When the list (vector) involved in a constraint `element` contains integers, one may decide to use an `extension` constraint. For our model, this would give:

```
[(s[i], f[i]) in {(j, fuel) for j, fuel in enumerate(fuels[i])} for i in range(nHouses)],
```

²This model is inspired from the one proposed by Ollagnier and Fages for the 2013 Minizinc Competition.

Chapter 4

Frequently Asked Questions

This chapter will contain frequently asked questions.

Q. Is it possible to post a constraint only if a condition holds?

A. Of course, it is always possible to put the condition outside the PyCSP³ function `satisfy()`. For example:

```
if test > 0:  
    satisfy(AllDifferent(w, x, y, z))
```

but it is also possible to use the Python conditional operator 'if else' while returning 'None' if the condition does not hold.

```
satisfy(AllDifferent(w, x, y, z) if test > 0 else None)
```
